**DELEGATION**, in civil law, an act by which a debtor, with the consent of a creditor, procures another debtor in his place, and is himself relieved from the charge. At common law, it is the transfer of property from one person to another. Any person may delegate to another authority to act for him in a matter which is lawful and otherwise capable of being delegated. But the one to whom a power is delegated cannot himself delegate that power to another, since the dependence of the party originally delegating was upon him only, and not upon a third person.

**DELESCLUZE**, LOUIS CHARLES, 1809–71; a French politician, journalist, and agitator, who took a prominent part in revolutionary conspiracies in the time of Louis Philippe, in those of the republic of 1848, and of the empire. He was imprisoned for one of his articles in the newspapers, and was once transported to Cayenne. In 1868, he started the *Réveil* newspaper, one of the most radical of prints. He was a conspicuously desperate and reckless leader of the commune during the siege of Paris. He was killed on a street barricade, whether by accident or design is not known.

**DELFE**, a heraldic charge, representing a square sod or turf, the term being derived, it is supposed, from the verb to *delfe* or dig. A delf tenné is the appropriate abatement for him who revokes his challenge, or otherwise goes from his word. See **ABATEMENT**.

**DELFI'CO, MELCHIORRE**, 1744-1835; an Italian writer on political economy. His first publication was a vindication of marriage against the loose views then prevalent. Another work, addressed to the king, had the effect of repealing vexatious restriction on the sale and exportation of agricultural produce. Other reforms of importance were due to his writings. During Joseph Bonaparte's brief reign he was councilor of state, and was employed in reconstructing the judiciary. When Ferdinand was restored he was made president of the commission of archives. He left a number of important critical works.

**DELFT**, one of the most ancient towns of s. Holland, is situated on the Schie, 8 m. n.w. of Rotterdam. It is intersected by numerous canals, the bridges over which are 69 in number. D. was once noted for its pottery (Delft-ware), but has now entirely lost its high reputation for this manufacture, and not more than 200 persons are engaged in the earthenware factories. D. is a dull town, but has several interesting buildings, one of which, the town-hall, is a picturesque and richly adorned edifice. The new church contains a monument more ornate than tasteful, to the memory of prince William I. of Orange, who was assassinated here 10th July, 1584. It also contains the tomb of Grotius, and the burial-vaults of the present royal family of Holland. The old church, a building of some note, contains the tomb of the naturalist Leeuwenhoek, and of the celebrated admiral Tromp. D. has also a state arsenal, a college where all matters connected with the management of the dikes are taught, a gymnasium, and infirmary. There are some manufactures of woolen cloths and tobacco-pipes. Pop. '74, 23,365.

**DELFTSHA VEN**, an old t. in s. Holland, is situated on the Maas, 2 m. w. from Rotterdam. It is defended from floods by three strong dikes. The principal buildings are the Reformed church, which is a handsome cruciform building, the Roman Catholic church, and the town-house. There is some trade and shipping; but the chief sources of wealth are distilling spirits, beer-brewing, iron-founding, ship-building, sawing wood, refining sugar, etc. Pop. '75, 9,440.

**DELGA'DA**, or **PONTA DELGADA**, a city in St. Michael, one of the Azores, on the s. side of the island; 37° 45' n., and 20° 40' w.; pop. 15,885. It has a large trade in fruit, grain, etc.

**DELHI**, the name of an executive district and also of a division or commissionership in the Punjab, formerly in the North-west Provinces.—The *district* is situated in 28° 24' to 28° 54' n. lat., and 76° 49' to 77° 29' e. long., having an area of 1227 sq.m., of which 821 are under cultivation. Of the waste lands, 189 sq.m. are capable, and 263 incapable of cultivation. The pop. in 1868 was 608,850, classified as follows: Sikhs, 582; Hindus, 447,079; Mohammedans, 133,912; and other classes, 25,034. The Christians, in the same year, numbered 2,243, of whom 648 were Europeans, 233 East Indians and others, and 1362 natives. To the s. the district is rocky and barren. The soil generally is sandy or rocky, and the most fertile portions are those to the n. and n.w., watered by the Jumna.—The *division* of D. contains 2,971 villages, has an area of 5,595 sq.m., and had in 1868 a pop. of 1,916,423, of whom 1,029,757 were males. It comprises the three executive districts of Delhi, Goorgaon, and Kurnal.

**DELHI** (ancient name, *Indraprestha*, or *Inderput*; Mohammedan name, *Shahjehana-bad*), a celebrated city of northern India, in 28° 39' n. lat., and 77° 18' e. long., capital of the province and district of the same name, is situated on an offset of the river Jumna, at about a mile from the right bank of that river, and at an estimated elevation of 800 ft. above the level of the sea. The modern city, which was founded by shah Jehan in 1631, has a circumference of about 7 miles. It is protected by ramparts, bastions, etc., and is entered by 11 gates. The greater number of the streets in D. are narrow, but the Chandni Chauk is an exception, being 90 ft. broad, and 1500 yards in length, and intersected by an aqueduct. The other principal street is 120 ft. wide, and 1 m. in length. D. has many monuments of its former magnificence. The mogul's palace was thought by bishop Heber to surpass the Kremlin. The Jumma Musjid, or principal mosque, was commenced by shah Jehan in the 4th year of his reign, and completed in the 10th, at a cost of £100,000. This magnificent building has been restored by the British government. The Delhi college was founded in 1792, and in 1829 the sum of 170,000 rupees was bequeathed to it by a minister of the king of Oude. The interest of this sum, together with grants from government, raises its annual revenue to 40,580 rupees. For each of the languages, English, Arabic, Persian, and Sanscrit, there is a separate department. According to the census of 1868, D. contained 154,417 inhabitants, of whom about one half are Hindus, and the other half Mohammedans. D. has railway communication, by the East Indian railway, with Calcutta, distant 1019 m.; with Bombay, distant 870 m.; and with intermediate places. The mean temperature of the day has been ascertained, by observations extending over three years, to be as follows: Jan., 56°; Feb., 61°; Mar., 72°; April, 83°; May, 91°; June, 92°; July, 86°; Aug., 83°; Sept., 83°; Oct., 77°; Nov., 65°; Dec., 58°. The vestiges of ancient D., on the e. bank of the Jumna, consisting of ruined tombs, gardens, serais, and palaces, cover

an area of about 30 m. in circumference, and present a remarkable scene of desolation. The modern city is noted for its needle-work, and here the shawls of Cashmere are embroidered in silk and gold. The D. goldsmiths are famous for the delicacy and beauty of their work. D. was the capital of the Afghan or Patan, and afterwards of the Mogul empire. It was taken by a British army under Lord Lake, Sept. 8, 1803, and has ever since—if we except the brief period it was held by the mutineers in 1857—continued under British rule.

In our own time, D. has been rendered memorable by the events of 1857. The march on the city of the mutineers from Meerut, the terrible 11th of May, the explosion of the powder-magazine by Willoughby and his heroic band, the tragic scenes that followed, the siege, the assault (Sept. 14), when the city was won (Sept. 20) gate by gate and quarter by quarter—a success saddened by the death of the gallant Nicholson; the subsequent daring capture of the king of D. by Hodson of Hodson's horse, and the capture and shooting of his miscreant sons by the same officer, are historical facts still fresh in the recollection of the world. See *The History of the Indian Revolt*, published by the Messrs. Chambers in 1859; *The Punjab and Delhi in 1857*, by the Rev. J. Cave Browne, M.A. (Edin. and Lond., 1861); *Twelve Years of a Soldier's Life in India*, edited by the Rev. George H. Hodson, M.A. (Lond., 1859).

**DELIA**, a festival of Apollo held in Delos. It included athletic and musical contests, for which the prize was a branch of the sacred palm. The Athenians, who ascribed its establishment to Theseus, took especial pains to maintain the splendor of this festival.

**DELICT**. The law of Scotland, following that of Rome, divides delicts into delicts proper and *quasi delicts*—the former being offenses committed with a positively malicious purpose, the latter being injuries inflicted by culpable negligence of so gross a kind as to amount almost to crime. The latter class of delicts, though inferring an obligation to repair the injuries sustained by the private party, do not generally form grounds for criminal prosecution. See **DAMAGES**.

**DEL ILAH** (Heb. the languishing) is the name of a Philistine woman whom Samson loved. By her flattering blandishments, she obtained from him the secret that his God given strength lay in his locks; and having cut these off while he lay asleep, she then treacherously betrayed the strengthless warrior into the hands of his enemies.

**DELILLE**, JACQUES, a French poet, was born at Aigues-Perse, in Auvergne, June 22, 1738, and received his education at the collège de Lisieux, Paris. He first occupied the position of instructor at the colleges of Beauvais and Amiens successively, and was afterwards appointed to a professorship in Paris, at the collège de la Marche. Here he published various poetical effusions, the most considerable of which was a translation of the *Georgics* of Virgil—a work which appeared in 1769, was distinguished by its grace and elegance of style, and met with a most enthusiastic reception. In 1774, he published *Les Jardins*, the success of which, however, was not equal to that of his *Georgics*. The comte d'Artois presented him with the abbey of St. Severin, or rather with its revenues, for he did not insist on D. becoming a priest. His poem *L'Imagination* was written during a visit which he made to Constantinople in 1784, in the suite of comte de Choiseul-Goubbier, the French ambassador to the Ottoman court. On his return, he was elected professor of *belles-lettres* at the university of Paris, and of Latin poetry at the college of France. At the revolution in 1789, however, he lost all his property. He afterwards removed to Switzerland, where, in 1800, he published *L'Homme des Champs*. In 1801, he visited London, published a translation of *Paradise Lost*, and in that same year, having been solicited to return to Paris, he re-entered the academy and the college there with which he had formerly been connected. He died 1st May, 1813.

**DELIQUESCENCE** is the term applied to the property which certain substances have of absorbing moisture from the air, and becoming damp, and even running into liquid. Caustic potash, and the chlorides of calcium and magnesium, are examples of substances which undergo this change.

**DELIRIUM** (from Lat. *deliro*, I am furious), a state of deranged mind, in which the intellect and the judgment are perverted or lost, while the imagination and the passions are often excited, or at least left without control. The result is an incoherent or totally disordered course of action and speech, frequently attended by delusions, or unreasonable belief in supposed facts, which the sound mind at once perceives to have no existence in nature. The nature, extent, and variety of the delusions, and the degree to which the control of the reason over them is lost, may be said to indicate the type of delirium to which the patient is subject; and in some instances, the cause of the disease is pretty decidedly shown forth by the prevailing impressions on the mind and senses. Referring to the article insanity for the description of maniacal delirium, or mania, and to the article fever for that of typhoid delirium, or typhomania, we may confine ourselves in the present article to a slight sketch of the delirium arising from habitual intoxication, the *d. delirium ebriosorum* or *potatorum* (of drunkards), or, as it is more commonly called, from the bodily tremors that accompany it, *delirium tremens*. This disease is not to be confounded with the mere paroxysm of intoxication, and still less, if possible, with the insane craving for drink, or dipsomania (q.v.). It is, on the

contrary, often found in persons who have not been recently intoxicated at all, though of persistently intemperate habits, and in whom the desire for drink, as well as for food, has been entirely suppressed by the access of the disease. It is a true though usually a temporary form of insanity or of mania, brought on by the habitual poisoning of the nervous system, over a long course of weeks or months, by alcoholic liquors; and it is not going too far to say that it is rarely, if ever, induced by a single debauch, at least in its aggravated form. Delirium tremens is characterized by a restless, irritable state of the nervous system, rather than by furious paroxysms of excitement (though these are not rare); by constant though ill-regulated and ineffectual attempts of the patient to occupy himself; by spectral illusions, or the vision and hearing of non-existent objects; by tremors of the hands and tongue; by prostration of appetite; and by great wakefulness, the want of sleep being often protracted over many days and nights, and forming, with the constant excitement of the senses, and the prostration of the vital powers from deficient nourishment, the true source of danger in this disease. The main elements in the cure are careful nursing, and the use of all means to secure sleep, and re-establish the digestion. Opium, hyoscyamus, and antimony, are used in some cases, and tonics with laxatives in others; chloroform has also been employed. In certain cases, stimulants are required for a time; but none of these remedies ought ever to be used except under the best medical advice, for there is little doubt that delirium tremens is one of the diseases where the rash employment of strong medicines is extremely dangerous to life, and where good nursing and food, without other remedies, will usually succeed. Where proper protection and vigilance cannot be otherwise secured, the patient should at once be transferred to the nearest hospital or lunatic asylum; and if the attacks have been repeated, he should be detained for some time after his recovery. See DELIRIUM TREMENS.

**DELIRIUM EBRIOSUM**, a term intended to denote a form of acute mania, having intoxication for its exciting cause. It is often mistaken for delirium tremens (q.v.), and doubtless has frequently been dealt with as such in criminal cases. It originates either from a single fit of intoxication, or a short course of intemperance—frequently of periodical occurrence—in those who are mentally excitable from hereditary peculiarity of constitution, or from some previous injury of the head, and who may have experienced some cause for depression of spirits. It is marked by an uncontrollable desire for drink, which, when gratified, only leads to further imperious demands, until the thing itself is loathed, and a fit of sickness brings about recovery. In the course of the paroxysm, however, more or less of indecorous conduct or wild and vicious passions are displayed; so that, unless the affected is restrained, and stimulants withdrawn, violence is apt to be offered to any one coming in the way. It is in this state that homicide and murder are so frequently perpetrated. On the delicate question of legal responsibility connected with this state, we do not here enter.

**DELIRIUM NERVOSUM or TRAUMATICUM**, a term given by baron Dupuytren, the celebrated French surgeon, to designate an attack of delirium with tremors, which frequently supervenes on severe bodily injuries, such as gunshot wounds, burns, and fractures—chiefly met with in large hospitals—in the case of persons of weakly constitution, and who are irritable and nervous, and have been intemperate in their habits. It has been considered by some as identical with delirium tremens (q.v.), but it only simulates that affection, being but a symptom of a sympathetic fever, having a typhoid character.

**DELIRIUM TREMENS** is the term given to a disease originating from the abuse of alcoholic stimulants by those of a nervous and irritable temperament, characterized by a combination of delirium with muscular tremors. The tremors are general, but chiefly of the hands, and of the tongue when protruded; and the delirium is of a muttering, sight-seeing, bustling, abrupt, anxious, apprehensive kind. The individual affected cannot follow out a train of thought, explain an illusion or perverted sensation, or perform any act correctly; and although at one moment partially conscious and rational, is the next incoherent and excited by the most ridiculous fancies of a spectral kind, such as visitors in the shape of devils, cats, rats, and snakes, or by alarming occurrences, such as robberies, fires, and pursuits for crimes. All this is ushered in and attended by complete sleeplessness; and during the attack, in an uncomplicated form, there is no violence or ferocity of demeanor (see article DELIRIUM EBRIOSUM), although mischief to himself or others may be done under false impressions; and he is easily pleased by gentleness and indulgence, and fretted by restraint and opposition. The face has generally a pale dirty color, and anxious expression; eyes startled but lusterless, sometimes considerably suffused, and the pupils not contracted, unless under treatment with opium, or when inflammation of the membranes of the brain has supervened; skin warm and moist, often perspiring copiously; tongue sometimes loaded, but generally pale, moist, and remarkably clean; appetite small, but the individual will often take whatever is presented to him; thirst by no means urgent, with seldom or never any craving for spirituous liquors; alvine evacuations bilious and offensive; urine scanty, high colored, and often albuminous; the pulse usually ranges from 90 to 120, and is generally soft, but of various degrees of fullness and smallness. The precursory symptoms are not peculiar to or pathognomonic of this disease, but common to many other febrile affec-

tions implicating the functions of the sensorium, of the circulation, of digestion; and the paroxysm—distinguished by the above phenomena—runs a remarkably uniform course, independently of age and constitution. In genuine uncomplicated cases—that is to say, when not precipitated by other illness, such as bronchitis, pneumonia, erysipelas, and fever; or some accident, such as contusions and fractures—when the illness is more of the nature of the delirium traumaticum (q.v.)—the paroxysm runs its course in from two to three days, and terminates in sleep, from which the individual generally awakens convalescent.

The above description has been taken from a paper by Dr. Peddie, of Edinburgh, referred to underneath, whose views shall here be further developed. Previous to its publication, the generally received opinions regarding the essential nature of D. T. were, that it is a disease of exhaustion or irritation of nervous power, and that it has the habitual abuse of intoxicating liquors for its predisposing, and the abstraction or diminution of the accustomed stimuli for its exciting, cause; and consequently, that the proper treatment consists in the continuation of stimulants—"a hair of the dog that bit"—together with large opiates to act on the same principle, and force on the salutary, or what has been called the critical sleep. Since then, however, a great revolution has taken place in the views of the medical profession regarding the pathology and treatment of D. T.; and in consequence of this, a fatal result in a genuine case of the disease now seldom or never occurs, where these views are understood and acted on.

It has been shown that the more the history and phenomena of the affection are examined, the greater will the difficulties surrounding the second part of the proposition above stated become. It has been shown that the affection is specific and peculiar, uniform in its symptoms and progress; and that it is essentially a form of nervous poisoning—a toxicological result from the accumulation of alcohol in the system through the continued abuse of stimulants. It has been observed that the alcohol—in whatever way it may be atomically changed or chemically combined—acts on the nervous pulp of the brain through the medium of the circulation, and sets up in it an alcoholism or alcoholic erethism, manifested by a certain amount and kind of exhaustion of the cerebral and muscular functions, together with decided over-action in the meningeal vessels; and that the alcoholic principle, although acting at first slowly, begins ere long to poison the gray matter of the brain, so that every additional drop thereafter brings it more and more into a poisoned condition, until at length, unless arrested by judicious treatment, the state of irritation tends to inflammatory action and serious encephalic mischief. While, therefore, the first part of the above proposition is true—though explainable in a very different way from formerly received opinions—the second part, viz., that the diminution or abstraction of the accustomed stimulus is the exciting cause of the disease, is altogether untenable. Analogy will not bear out the assertion. Mercurial fumes, or the oxides of mercury, when long inhaled or absorbed into the body, as in the case of quicksilver miners, gilders, and others, in the course of time produce an attack of shaking paralysis—the *tremblement mercuriel* of the French pathologists; but will the workmen thus long exposed be more likely to become affected with tremors when removed from this poisonous atmosphere and occupation, than if continuing at their work? The reverse is well known to be the fact, not only in the case of such artisans, but of those who are beginning to suffer in a somewhat similar way from lead-poisoning. In both affections, when the symptoms are precursory or recent, a cure can be effected only by removal from the injurious occupation; otherwise, the symptoms deepen with hourly increasing rapidity, until tremors are succeeded by sleeplessness, delirium, and ultimately coma. Then, too, for example, salivation from any of the preparations of mercury, and narcotism from any opiate, are not intensified by withdrawing these agents after a certain point is reached. On the contrary, a continuation beyond that stage, particularly in some kinds of constitution, more rapidly develops their peculiar physiological manifestations; and now, an infinitesimal dose will do what a large dose in an earlier stage could not. Thus is it with alcoholic stimulants in the production of delirium tremens. In those of a highly sanguine temperament, and of a nervous irritable disposition, the effect of a certain length of indulgence is to induce this condition (just as in subjects with the tendency to gout, a certain amount of high-living is apt to produce an attack of that affection), and beyond that stage, a small quantity of alcoholic stimulus will keep up and deepen the effect, which, previously, a large dose would not do, or, in another individual, could not produce, whatever quantity is imbibed. Thus is explainable the very common erroneous statement made in regard to an individual affected with D. T.; that although for a considerable time he had systematically indulged in considerable quantities of spirits, wine, or malt liquor, or in all of these, yet for a week or two he had drunk very sparingly, and, within the last few days, little or none; indeed, that he was now suffering from the withdrawal of his wonted stimulus, in meritorious efforts to free himself from a habit of which he had begun to be ashamed. All this seems plausible; but the statement should rather have been that, although consuming large quantities of drink at one time, he had felt latterly a smaller quantity affect him; that he then reduced still further the amount, but experienced an equal if not greater constitutional effect therefrom; and thus, from day to day, reduction was forced on him by his own sensations of gastric irritation, nervous excitement, and muscular debility—these feelings being, in fact,

neither more nor less than the premonitory symptoms of an attack of D. T., and just what might be looked for on the view that the alcoholic principle is in such instances a cumulative poison, and the exciting as well as the predisposing cause of the affection. That such is the true solution of the problem, cannot be doubted; and if a suspension or diminution of habitual supplies of stimulants be at any time followed by symptoms of D. T., this is not to be regarded as the result of the change in the practice of the individual, but as occurring in spite of it, and because the constitutional effect is already produced, and the premonitory stage of the disease begun. In a considerable number of instances, drink is taken freely up to the period when the disease is developed, there being no diminution of the quantity consumed, and no interval in the practice; and when there really is some diminution from the amount of previous supplies, it is on account of the system being already affected so much that a less quantity now produces a greater or equal effect. On the other hand, it may be safely averred, in contradiction to the popular error, that although stimulants are at once taken away from the habitual dram-drinker, a paroxysm of D. T. will not be produced if the peculiar diathesis is not yet established, and the precursory symptoms of the disease are not already begun. He may experience much mental disquietude and physical discomfort, and feel weak for a time, just as a gourmand would feel lowered and depressed by the abstraction of his accustomed good living; but this would soon pass off, without the occurrence of the usual signs of D. T., more especially without those spectral illusions or phantasms, which are common to poisonings with several other agents of the narcotico-acrid class.

It seems unnecessary to add more on this part of the subject, than that experience derived from some of our large prison-establishments shows that while fully three-fourths of the criminals committed belong to the intemperate classes, and a large number, especially of the debtor class, are habitual drinkers up to the moment of admission, no bad effects are observed from the sudden withdrawal of the wonted stimuli, and the substitution of prison-fare.

In regard to the treatment of this remarkable disease, it is evident, from a common-sense consideration of its phenomena and pathology, that the non-stimulating and non-opiate plan must be the safest and best. If more spirits deepen the paroxysm, by producing greater cerebral determination, then why administer even one drop additional? And if opiates combined with spirits, or given alone, act in the same manner, and tend to occasion congestion in the blood-vessels of the brain, why run the risk of inflammation, convulsions, and coma, in an endeavor to force on the salutary sleep? It must not be overlooked that this sleep is the normal termination of the paroxysm, and is not to be viewed as a part of the affection, or in the same light as we are accustomed to regard a critical sweat or other discharge. It indicates diminished activity of the cerebral circulation and functions, and the commencement of convalescence. Hence, in a large proportion of instances, the sleep will take place spontaneously, and it will be safer to do nothing at all. The object, therefore, of treatment should rather be to remove all hindrances to sleep than to force it. In the more severe cases, this is best done by a moderate and well-regulated course of tartrate of antimony, the action of which, in this affection, appears to be remarkably sedative. It greatly diminishes excited action, induces weariness of muscle, general nervous exhaustion, and mental languor. It thus removes all obstacles to the occurrence of the salutary sleep, and favors it; and when the individual exhausted seeks his couch, he finds repose—not as a drugged sleep, but naturally and profoundly—awaking in general with restored reason and muscular control. Digitalis has been given with the same view, also ipecacuanha and aconite; but none of these answer the various ends so well as antimony. In the milder cases, however, no medicine is required, and it seems enough to do in such, what is essentially necessary in the severer attacks—to support the strength—the organic functions of life—by suitable nourishment, such as soups, *café au lait*, and white-of-egg, and to soothe in every possible manner the excited feelings of the patient. Nothing is more hurtful in delirium tremens than restraint, particularly that of the strait-waistcoat. It increases the cerebral excitement by the never-ceasing struggles for liberty which ensue, so that fatal convulsions have very frequently been the result. All the control required is the presence of one or two judicious attendants, who will humor the patient in his whims and fancies; who will speak and act regarding them so as to assure him of safety, and to relieve him of that apprehension which is the most characteristic feature of the delirium; and who will mildly but firmly interpose, if he attempts anything which may accidentally prove injurious to himself or others. The apartment, however, in which the patient is confined should be well secured, for he may rush out at the door, or leap from a window, in the fright and frenzy of imagined danger. The larger, too, the room is, the better, that he may have space to advance and retreat, according as he wishes to scrutinize or avoid a suspicious or distressing object of his fancy; to arrange and rearrange the furniture; or to carry on, after a fashion, the imaginary duties of some bustling occupation. Besides this, there should be abundance of light, so as to dissipate terrifying hallucinations. The expenditure of muscular effort without any restraint, aids greatly in producing a safe kind of mental and physical exhaustion; and the individual, languid and worn-out, lies down voluntarily, and falls into the desired and

restorative sleep.—*The Pathology of Delirium Tremens, and its Treatment without Stimulants or Opiates*, by A. Peddie, M.D., pp. 51, 8vo.

**DELISLE.** See LISLE, GUILLAUME DE.

**DELITZSCH** (named after the Slavonic *Delecezen*, once dominant there), a t. of Prussian Saxony, 15 m. n. from Leipsic, with which it is connected by railway, on the right bank of the Lobber, a small river. It is an old but well-built town, and has manufactures of tobacco, woolen cloth, and hosiery. It is the capital of a circle, for the most part flat, but producing much corn and fruit. Pop. '75, 10,312.

**DELITZSCH, FRANZ**, b. 1813; a German theologian, educated in Leipsic; in 1846, professor of theology at Rostock. In 1850, he became one of the strongest supporters of what is called the Erlangen school, or the strictest orthodox theology. He has written much on theology, and on oriental philology. In 1863, in company with Kiel, he began the preparation of a complete commentary on the Old Testament. To profound learning he adds critical acumen.

**DELIUS, NIKOLAUS**, b. Bremen, 1813; a graduate of Bonn, and since 1855 has held the professorship of Sanscrit, and of Provençal and English literature, in that university. He has published in German a critical edition of Shakespeare.

**DELIVERY.** See PARTURITION.

**DELIVERY IN SALE.** See SALE OF GOODS.

**DELIVERY OF A DEED.** See DEED.

**DELLA CRUSCAN SCHOOL.** About the year 1785, a number of English residents at Florence endeavored to amuse their lagging hours by writing verses, which they published under the title of *The Florence Miscellany*. The insipidity, affectation, and fantastic silliness of these productions transcend all belief; yet such was the poetic destitution of the period, that they soon found a crowd of admirers and imitators. Taking the name of an academy at Florence (see ACADEMY), the Della Cruscans now began to print their precious lucubrations in England, chiefly in two daily newspapers called *The World* and *The Oracle*. "While the epidemic malady was spreading from fool to fool," as Gifford pungently says, one of the brotherhood, a Mr. Robert Merry, came over from Florence, and "immediately announced himself by a sonnet to Love." It was answered by a certain Anna Matilda, who (as was the custom) praised it immoderately in language even more absurd than Merry's own. According to Gifford, "the fever now turned to a frenzy: Laura, Maria, Carlos, Orlando, Adelaide, and a thousand other nameless names, caught the infection; and from one end of the kingdom to the other all was nonsense and Della Crusca." Retribution, however, came (for Nemesis watches the course of poetry as sharply as that of politics). In 1794, Gifford produced his *Baviad*, and, in 1796, his *Mecivud*. Rarely has literature witnessed such a scalping. It completely killed the school, and, indeed, it is only in these two poems that the memory of most of the unhappy Della Cruscan songsters has been preserved—an immortality which may be compared with that conferred by the *Æneide Calendar*.

**DELLYS**, a seaport t. of Algeria, 49 m. e. from Algiers. The French part of the town has wide streets, and a square planted with trees. The Arab part, which is greatly more populous, retains its old character: its streets are narrow and tortuous. The climate of D. is reckoned very salubrious. The vine and the olive succeed well in the neighborhood. *Becheña*, a kind of sorghum or durra, is grown. There is a trade in grain, oil, and salt. Pop. 10,484, of whom 862 are Europeans.

**DEL NORTE**, a co. in n.w. California, on the Oregon border and the Pacific ocean, intersected by the Klamath river; 1440 sq. m.; pop. '70, 2,022. The surface is mountainous, and mostly covered with timber. Gold and copper are plentiful. Agriculture is the chief business. Co. seat, Crescent city, on the Pacific.

**DELOME, JEAN LOUIS**, b. at Geneva in 1740, was originally an advocate in his native town, but on account of certain political disturbances which took place there, and in which he had shared, he was forced to leave it. He went to England, where, in spite of his literary activity, he lived for several years in great poverty. He returned to his native country in 1775, and died at a village in Switzerland, July 16, 1806. D.'s principal work is *Constitution de l'Angleterre, ou État du Gouvernement Anglais comparé avec la Forme Républicaine et avec les autres Monarchies de l'Europe* (Amsterdam, 1771); English translation by the author himself (Lond. 1772). In 1772, he also published in English, *Parallel between the English Government and the Former Government of Sweden*; ten years later, his *History of the Flagellants, or Memorials of Human Superstition*; and, in 1796, an *Essay containing Strictures on the Union of Scotland with England*. His work on the British constitution, although not reckoned of great value by English critics, contains some acute observations regarding the advantages of a limited monarchy.

**DELORME, MARION**, a Frenchwoman, whose name figures too prominently in the history of the 17th century. She was born about 1612, at a village near Châlons-sur-Marne, and came at an early period of her life to Paris, where her great beauty was easily secured for her a good match, had she not been inclined to a life of licentious intrigue. Almost all the distinguished men of the age were her "lovers." During the first disturbances of the *Frondeurs*, her house was the rallying-point of the chiefs

of that party, and in consequence, Mazarin was about to imprison her, when she suddenly died at the age of 39. A curious tradition sprang up in France during the next century, to the effect that Marion had *not* died, but escaped to London; that she had returned to Paris in 1682; that she, meanwhile, had been thrice married—first, to a lord, second, to a robber-chief, and third, to a procurator of finance; and, finally, that she died in 1706, or, as others say, in 1741, when in her 129th year. Victor Hugo has made her the subject of one of his historical dramas.

DE LOUTHERBOURG, PHILIP JAMES, 1740–1812; of a Polish family, but b. at Strasburg, where he was naturalized, educated in the university, and intended for the ministry. His inclinations, however, led him to painting, and he studied in Paris under Van Loo. He speedily made a name and won high rank. He was elected to the French academy while under the required age. He had some eccentricities, which constantly appeared in his work, especially in his titles, as, when he painted a group of asses he called them "Father and Mother," "Little Fanfan," "Aunt and Uncle from Brittany, Cousin Germain," and the "Perruquier of all the Family." He traveled in Switzerland, Germany, and Italy, and became celebrated more for mechanical construction than for painting. One of his mechanical contrivances was a model theater, where he cleverly represented the moon and stars by lights, and running water by sheets of metal and gauze with loose threads of silver. In London, he was employed by Garrick to superintend the mechanism and scene-painting of Drury Lane, which he did with remarkable success, making a new era in the adjuncts of the stage. The Christmas pantomime of 1781 introduced these novelties, to the surprise and delight not only of the public, but also of artists. The green grass actually became russet, the moon rose and lighted the edges of the passing clouds, and all England was captivated by effects which we now scarcely notice. A still greater triumph was in his mechanical representation of the rise, progress, and result of a storm at sea—the one which had just destroyed a great East Indian. The same show gave "The Fallen Angels raising the Palace in Pandemonium." At the same time his painting went on, and he produced "Lord Howe's Victory off Ushant," and other large pictures for the Greenwich hospital gallery. His restless spirit led him to dabble in magic, and he joined the famous Cagliostro for a time. He sought the philosopher's stone, and found a reason for his ill-success in the fact that a relative stole in upon him and broke his crucible at the critical moment.

DE LOS (called also in ancient times Asteria, Ortygia, Cynthus, etc.), an island in the Grecian archipelago, the smallest of the Cyclades, is situated between the islands Rhe-neia and Mykonus, in lat. about 37° 23' n., and long. 25° 17' east. According to the mythological account, it was at first a floating island, but was fixed to the bottom by Zeus, in order that it might become a safe abode to Leto, who, about to bring forth Apollo and Diana, was seeking a refuge from the wrath of Hera. Its earliest historical inhabitants were Ionians, and it appears to have been the center of a great periodical festival held in honor of Apollo, both on the mainland and in the islands. In 426 B.C., D. was purified by the Athenians, all the tombs were removed from it, and it was declared pollution for any birth or death to take place on it. Four years after, the inhabitants of Athens expelled the Delians from the island. After 146 B.C., when Corinth fell, D. became the seat of extensive commerce. Its sacred associations, its great festival, its excellent harbor, and its situation in the direct route from southern Europe to the coasts of Asia, all combined to render it a port highly favored by merchants. So great was the traffic of D., that it is said 10,000 slaves changed hands here in one day. After flourishing for a considerable time, it was devastated in the Mithridatic war, and from this calamity it never recovered. Pliny describes D. as being merely a rock, and only 5 m. in circumference. It was noted for its palm-trees, and also for its brass and the brazen vessels which it manufactured. The town of D., which stood at the foot of Mt. Cynthus, a granite crag of from 400 to 500 ft. high, is now a mass of ruins. Still, however, the remains of the great temple of Apollo, and of the colossal statue raised in his honor, may be distinctly traced, although shiploads of the more perfect architectural fragments were conveyed, centuries ago, to Venice and Constantinople. A few shepherds and goatherds from Mykonus are now the only inhabitants of Delos.

DELPHI (now CASTRI), an ancient t. of Phocis, Greece, celebrated chiefly for its famous oracle of Apollo, was situated about 8 m. n. of an indentation in the northern shore of the gulf of Lepanto (Corinthian gulf), at the southern base of Parnassus, in lat. 38° 27' n., and long. 22° 37' east. Its original name, and that by which Homer invariably speaks of it, was Pytho. It stood in the center of a district renowned for its classical associations. Occupying the vale of the Pleistis, it was seated in a semicircle like the area of a grand natural theater, backed towards the n. by two lateral spurs of Parnassus. These lateral ranges extend e. and w. around D., and give rise also, from the point at which they approximate, to the famous fountain of Castalia, the holy water of the Delphian temple. The earliest inhabitants of D. are said to have come from Cyreoria, a town upon one of the slopes of Parnassus, the inhabitants of which are supposed to have been Dorians. From the Delphian nobles were at first taken the chief magistrates and the priests of the temple, while the pythia or female who delivered the oracle, at first always a young maiden, but latterly always a woman not younger than 50, was usually selected from some family of poor country-people. In the center of the

temple was a small opening in the ground, whence arose an intoxicating vapor; and the pythia having breathed this, sat down upon the tripod or three-legged seat, which was placed over the chasm in the ground, and thence delivered the oracle, which, if not pronounced at first in hexameters, was handed over to a poet, employed for the purpose, who converted it into that form of verse. As the celebrity of the Delphic oracle increased, D. became a town of great wealth and importance. In the 8th c. before the Christian era, it had become famous not only in Hellas, but also among the neighboring nations. Here the Pythian games were at first celebrated in 586 B.C. The first stone temple at D., built by Trophonius and Agamenes, was destroyed by fire in 548 B.C., but was rebuilt at the cost of 300 talents, or £115,000, and was fronted with Parian marble. In 480 B.C., Xerxes sent a portion of his army to plunder the temple; but as they climbed the rugged path that led to the shrine, a peal of thunder broke overhead, and two huge crags tumbling from the heights crushed many of the Persians to death, while the others, struck with terror, turned and fled. It was plundered by the Phocians during the sacred war, and was attacked by the Gauls in 279 B.C., who, approaching by that route which the Persians had on a former occasion adopted, were repulsed by a similar supernatural agency. D. subsequently excited the rapacity of many potentates, and suffered severely by their attacks. Nero carried off from it 500 statues in bronze; Constantine also removed many of its works of art to his own capital. In the time of Pliny, the number of statues in D. was not less than 3,000, and within the temple for a long time stood a golden statue of Apollo.

The modern town of Castri now occupies the site of Delphi. Its situation is beautiful, and from it the traveler may command an excellent view of the ancient valley. Castri stands in the immediate neighborhood of the source of the still flowing Castalian spring.

**DELPHIN CLASSICS**, an edition of the Greek and Roman classics, prepared by 39 of the best scholars of the time, under the editorship of Bossuet and Huet, tutors to the dauphin (q.v.), son of Louis XIV. The title-pages bear the words, "*In usum Serenissimi Delphini*," and hence the name. They have never been reprinted as a whole in England, but octavo editions of particular authors, such as Virgil and Horace, have been published for the use of schools. The D. C. possess little value in the eye of a scholar of the present day.

**DELPHINAPTERA**, a genus of *cetacea*, of the family *delphinidae*, agreeing with *beluga* (q.v.) in the want of a dorsal fin, but differing in having the snout produced into a slender beak, which is flattened transversely, and separated from the head by a marked furrow. *D. peronii*, the RIGHT WHALE-PORPOISE of the South sea whalers, is an inhabitant chiefly of the seas of high southern latitudes, but sometimes found even on the coasts of New Guinea. It is about 5 or 6 ft. long, black, with brilliantly white belly and snout. Its mouth is furnished with a great number of slender sharp teeth. *D. commersonii*, also found in high southern latitudes, is about the size of a porpoise, silvery white; the snout, tail, and pectorals tipped with black, and is described as one of the most beautiful inhabitants of the ocean. *D. borealis* was discovered by the United States exploring expedition in the North Pacific ocean.

**DELPHINIA**, a festival of Apollo, held annually on the 7th of April, at Athens, where the god was styled Delphinios. All that is known is that a number of girls carrying branches went in procession to the temple seeking to propitiate Apollo, it is supposed because of his influence over the sea, as this was about the time of the yearly opening of navigation. (From *Encyclopædia Britannica*.)

**DELPHINIDÆ AND DELPHINUS**. See DOLPHIN.

**DELPHINIUM**. See LARKSPUR.

**DELPHINORHYNCHUS**, a genus of *cetacea* of the family *delphinidae*, having one dorsal fin like the true dolphins, but the beak not distinguished from the forehead by a furrow. *D. bredanensis*, or *D. rostratus*, a species about 8 ft. long, black above and reddish below, has been thrown ashore on the French Atlantic coast. A much larger species, *D. coronatus*, attaining the length of 30 to 36 ft., is described as one of the whales of high northern latitudes, having been seen in numerous flocks among the ice-islands near Spitzbergen.

**DELTA** is the alluvial deposit formed at the mouth of a river from the deposition of the particles which it has held in suspension. The term was originally applied to the tract of land thus formed by the Nile, which, being inclosed by two main branches and the sea, has the form of the Greek letter Δ, delta. The formation of deltas depends more upon the presence or absence of currents met with at the mouth of the river, than upon the quantity of sediment held in suspension when it reaches the sea. Deltas are consequently of almost invariable occurrence in inland lakes, in the quiet estuaries of the nearly tideless Mediterranean, and in the sheltered bays and gulfs of other seas. When, on the other hand, there are strong ebb-tides, or powerful oceanic currents, the detritus is carried off into the sea.

**DELTA**, a term applied to the land lying between the two or more mouths of a river, generally of triangular form, like the Greek letter Δ (delta). They are usually constantly increasing alluvial deposits pushed out into the sea by the action of the rivers.

That of the Ganges is the largest, its base on the ocean being 200 m., and its sides about equal. The deltas of the Nile and the Mississippi are also very large.

**DELTA**, a co. in Michigan, on lake Michigan and Green bay, indented by two other bays, intersected by a branch of the Chicago and Northwestern railroad; 1500 sq.m.; pop. '74, 4,741. It is hilly, well wooded, and contains abundance of sandstone and limestone. Co. seat, Escanaba.

**DELTA**, a co. in n.e. Texas, formed since 1870, lying on the forks of Sulphur river, about 250 sq.m. The soil is good, producing cotton, corn, etc. Co. seat, Cooper.

**DULUC, JEAN ANDRÉ**, 1727-1817; a native of Geneva, Switzerland, geologist and meteorologist. He was a merchant until nearly 50 years of age; but within that time, assisted by his brother, he collected a fine museum of mineralogy and natural history. After some political reverses he removed to England in 1773; where he was made a fellow of the royal society, and appointed reader to queen Charlotte, a position held by him for 44 years, and affording him ample time for study. Later in life he traveled in the principal European countries, and made a geological tour of England. He lived at the time when modern science was first seriously questioning the literal meaning of the six days of 24 hours each in the Mosaic account of creation; and he clung to the old idea, but was obliged to fall back upon a theory of wonderful volcanic action to account for the existence of the present continents.

**DELUGE** (through the French, from Lat. *diluvium*, a washing away, a flood). There is scarcely any considerable race of men among whom there does not exist, in some form, the tradition of a great deluge, which destroyed all the human race except their own progenitors. That the Noachian deluge, recorded in Scripture, covered the whole earth, was the universal opinion until towards the close of the last century. The organic remains, on which the science of paleontology is now founded, were regarded as its wrecks, and were held to prove that it had covered every known country, and risen over the highest hills. In the progress of geology, it soon became evident that most of the stratified rocks demanded an earlier origin than a few thousand years, and the influence of the deluge was consequently restricted to the slightly altered superficial deposits; but many of these were, after a few years, found to belong to a period vastly anterior to any historical epoch, and to have been produced by long-continued and steady agencies, differing totally from a temporary deluge. The present tendency of opinion among writers like the late Hugh Miller, is to regard the flood of Noah as partial and local, although the universality seems to be implied in the biblical description.

**DELUNATICO INQUIREND0**. See **INSANITY** (legal).

**DELUNDUNG**, *Prionodon gracilis*, a carnivorous animal inhabiting the forests of Java, referred to the family *viverridae*, but regarded as a connecting link between that family and *felidae*. It is of slender form, with a long cylindrical tail, and is prettily streaked and spotted.

**DELVINO**, a t. of European Turkey, in the province of Albania, beautifully situated on a hill-slope covered with olive and orange groves, about 47 m. n.w. from Janina. It is fortified, is the seat of a Greek bishop, and has a considerable trade in olive-oil. The women's dress is peculiar, being a long white wrapper, enveloping them from head to foot, and giving them the appearance of animated monumental figures. Pop. estimated at 7,500.

**DEMADES**, a Grecian orator and demagogue of the 4th c. B.C.; a man of genius, but entirely unscrupulous, and ready to sell his political influence to the best customer. He was a favorite with Alexander, and for a bribe saved Demosthenes and other Athenian orators from vengeance. He was deprived of civil rights by the citizens of Athens, but was restored on the approach of Antipater, and sent to him with Phocion, as ambassador. Antipater had no difficulty in bribing him; but on a later occasion he found out his duplicity, and put him with his son to death.

**DEMAND AND SUPPLY**. The nature and influence of the law or agency so designated by political economists have been the subject of considerable dispute. It has sometimes been maintained as a ruling principle, that the demand for anything creates the supply. This has been denied, however; and it has been held that, on the contrary, the supply precedes the demand, since the article must be in existence before a purchaser goes to ask for it. Steam-engines, for instance, and India rubber galoshes, must have been invented and made before any one thought of purchasing them. The most convenient way, perhaps, of viewing the term demand and supply, is to consider it as applicable to articles in the market; and here we shall find that the demand and the supply are continually vibrating with a tendency to balance. Sometimes there is more of an article than will sell at a remunerating price, sometimes less; but there is always a strong tendency to a balance. Thus, on any day in London, the supply of beef or of fish may be less than the demand—that is to say, the trade may be so brisk that had there been a few more bullocks at Smithfield, or a few more salmon and turbot at Billingsgate, they might have been sold at remunerating prices. At the same time, there may happen to be an excess of both commodities at Windsor. It never will happen,

however, that a supply suited for the London market will find its way to Windsor, or that no more will reach London than might feed Windsor—it would be as rational to expect the river Thames to reverse its course. This is the great law, then, by which the world is supplied with the necessaries of life. Every day the proper supply for the enormous consumption of London is on its way from the uttermost ends of the earth, as systematically as the sap is ascending to penetrate through all the branches of the tree. How impossible it would be to effect the same thing by artificial organization may be illustrated from the Russian campaign of Napoleon, where, despite of the most skillful and costly arrangements, one portion of the army were starving to death, while another were slaughtering their bullocks and leaving them to rot! It is necessary to keep in view the proper function of this law, which is in some measure defined under Competition (q.v.). The demand will not produce everything: no money will bring forth when wanted a Milton's *Paradise Lost*, or a Raphael's "Transfiguration." On the other hand, there are services beneficial to the world, or to a community, for which there is no demand in the commercial sense. There is a demand for almanacs, but none for the astronomical investigations on which they are founded. There is a demand for teachers of Latin and Greek, and for Latin and Greek school-books, but none for the profound scholarship necessary for keeping the knowledge of these languages alive; hence come scientific and scholastic endowments and establishments.

**DEMARCATIION, LINE OF**, an imaginary line running due n. and s., 360 m. w. of the Azores, established by pope Alexander VI. in 1494. All new lands discovered e. of this line were to belong to Portugal; all on the w. to Spain.

**DEMAVEND, MOUNT**, an extinct volcano of Persia. It forms the loftiest peak of the Elburz chain, which separates the low shores of the Caspian sea from the high table-land of Persia. Although no longer subject to eruptions, D. bears traces of its having been an active volcano within the most recent geological epoch. Its summit is conical, covered with sulphur, and rent by heated fissures. The crater is still visible, and the surface of the mountain is in many places covered with scorice. At its base hot springs give evidence of the continued existence of volcanic fire at no great distance beneath the surface. A great deposit of sulphur covers the summit of D., and is brought down to the plains in bags to be disposed of as an article of commerce. Although the path that leads to the peak is, for this reason, familiar to the inhabitants of the adjoining districts, the mountain was not ascended by any European till 1837. In Sept. of that year, Mr. William T. Thomson of the English embassy at Teheran, with the view of taking important bearings from a point which commands an extensive view of the shores of the Caspian, determined to reach the summit. He set out from the base with four guides, three of whom deserted him when they experienced the effect of the rarified atmosphere on their breathing. The first night he slept below the snow limit; the second night in a sulphur cavern near the summit, so highly heated that it was impossible to place the hand near a crevice of the interior. On leaving this place of shelter, the traveler's wet clothes were instantly frozen with a bitter blast from the Caspian. The height, as recently determined by the Russian survey, is 21,000 feet.

D. towers high above the neighboring mountains, the adjacent summits not exceeding two thirds of its elevation. At all times it has been a conspicuous object from the great trade route between India and the west, along the edge of the Persian table-land. It is not then to be wondered at that it is connected with the earliest Persian as Etna is connected with the earliest Greek traditions. There seems indeed more than an accidental coincidence between the fables which relate to the two mountains. According to the Greeks, the giant Typhon was buried under the volcanic region of Sicily, and the earthquakes and eruptions were caused by his efforts to escape. Fire proceeded from his mouth, and he was figured with one hundred snakes growing from each shoulder. Zohak, a personification of the bad principle, was in the same way supposed by the Persians to be buried under Demavend. He was figured with one serpent growing out of each shoulder; and in other respects he had much in common with the Greek monster.

**DEMBĒA, or TZANA, LAKE OF**, in Abyssinia, is in lat. 12° n., long. 37° 15' e., and is 50 m. in length, with an average breadth of 25 miles. It occupies part of an extremely fertile plain, situated at an elevation of some 6,000 ft. above the sea, and contains several beautiful islands, one of which is inhabited. Its southern portion is traversed by the Blue Nile.

**DEMBINSKI, HEINRICH**, a Polish gen., best known in Britain through his connection with the Hungarian revolution, was b. in the palatinate of Cracow, 16th Jan., 1791, entered the Polish army in 1809, took part in the invasion of Russia by the French in 1812, and was made capt. by Napoleon himself on the battle-field of Smolensk. He subsequently distinguished himself at Leipsic. After the fall of the empire, he returned to his native country, and lived in comparative obscurity for some time. The Polish revolution of 1830 called him again to arms. He obtained the command of a brigade of cavalry, and exhibited heroic courage at the battle of Kuflew. Afterwards, he made the campaign of Lithuania, under Gielgud; and arriving in Warsaw—having traversed

the entire Russian lines—was made commander-in-chief of the national army. After the surrender of Warsaw to the Russians, D. went to France, where he published his *Mémoires sur la Campagne de Lithuanie* (Strasbourg, 1832). In 1833, he proceeded to Egypt, and entered the service of Mehemet Ali, but returned to Paris in 1835. On the outbreak of the Hungarian insurrection, he offered his services to that country, and Kossuth appointed him commander-in-chief of the Hungarian army. He drew up a plan of the campaign, but could not obtain the concurrence of Görgei, whose tardy arrival caused the loss of the battle of Kapolna (26th–28th Feb., 1849). Forced to retreat behind the Theiss, D. resigned his command, but subsequently consented to act under Messaros. He strongly urged the necessity of uniting the cause of Hungary with that of Poland, and proposed to lead an army into Galicia; but his advice was not taken. After the resignation of Kossuth, and the capitulation signed by Görgei at Vilagos (13th Aug., 1849), D. fled to Turkey. In 1850, he returned to France, and commenced to write his *Mémoires* on the Hungarian war. He continued to live in Paris till his death, which took place 13th June, 1864.

**DEMEMBRÉ**, or **DISMEMBERED**, a heraldic term to signify that the members of an animal are cut from its body.

**DEMENTIA**. See **INSANITY**.

**DEMERA'RA**, a district and river of British Guiana (q.v.). The river D. is upwards of 200 m. in length, is  $1\frac{1}{2}$  m. broad at its mouth, and is navigable by ships of considerable burden for 100 miles. Its affluents are numerous though small, and at its embouchure into the Atlantic it affords a spacious harbor, obstructed, however, by a bar. It has many settlements on its banks.

**DEMESNE** (Lat. *terre dominicales*. *Dominicum*), in the present day, may be said to be the right which the owner in possession of lands in fee simple has in his estate. But the original signification of demesne was that portion of the lands of a manor (q.v.) which the lord of the manor reserved for his immediate use and occupation. The lands so reserved were either cultivated by the lord of the manor or his villeins (see **SERV**), and were thus distinguished from lands granted or subfeued to vassals for services to be rendered. So long as the practice of sub-infeudation continued, the demesne lands were a distinct and separate right; but the statute *Quia Emptores*, 18 Ed. I., having abolished sub-infeudations, and declared that on every transfer of land the feoffee should hold of the lord paramount, all lands became of necessity demesne, being in the actual possession of the owner or his tenants.

**DEMESNE**, **ANCIENT**, a species of copyhold tenure (q.v.). Lands held in ancient demesne are said to have belonged originally to vassals of the crown. The services rendered were determinate, not variable at the will of the lord, and more honorable than those of copyhold in general. The tenants also were entitled to certain privileges and exemptions from feudal services. But in process of time, the character of the services appears to have varied; so that in the present day tenants in ancient demesne in some instances differ little from ordinary copyhold tenants.

**DEME'TER**. See **CERES**.

**DEME'TRIUS**, the assumed name of four different persons who figure prominently in Russian history between the years 1603–13. In 1584, Ivan the "terrible" died, leaving two sons, Feodor and Demetrius, the former of whom ascended the throne, but proved a weak ruler, and was completely under the control of his brother-in-law Boris Godunoff; the latter, D., was brought up at a distance from the Muscovite court, and when only 9 or 10 years old, either accidentally killed himself, or, which is more probable, was put to death. In 1598, Feodor died also, and Boris ascended the throne, but his tyrannical measures rendered him very unpopular. In 1603, a strange story reached Russia. It was affirmed that D. was not dead, but had appeared in Poland. The fact was, that a person calling himself D., but who, it was asserted, was in reality a monk, named Grishka Otrepiev, belonging to the convent of Tchudoff, had found means to persuade prince Wisniewski in Lithuania, and afterwards Mniszek, palatine of Sandomir, that he was the true son of Ivan. The latter introduced him to Sigismund III., king of Poland, who saw in him a useful instrument for introducing Polish influence into Russia, and so aided him in his designs against Boris. Towards the close of 1604, he invaded Russia, repeatedly defeated Boris (who died April, 1605), and entered Moscow in June, the people receiving him with every demonstration of enthusiasm. He ruled for some months with vigor; but his manifest predilection for the Poles soon excited the Russians against him, and the arrival of his bride, Marina Mniszek, the daughter of the palatine of Sandomir, on the 12th of May, 1606, brought the discontent to a head. Sixteen days later, an insurrection broke out in the capital, headed by prince Wasili Shuiski. D. was slain, and a multitude of the Poles massacred. Wasili Shuiski now ascended the throne; but in the following year, an individual appeared, alleging that he was D., and that another had been mistaken for him in the Moscow massacre. He found a considerable number of adherents, especially when Marina acknowledged him to be her husband. The Poles also helped him, and for some time it seemed likely that he would succeed; but at length he was put to death at Kaluga, in 1610. The third false

**D.** gave himself out to be the son of the first. After a brief career, he fell into the hands of the czar, and was strangled. The *fourth* made the same pretensions, but falling into the hands of the Cossacks, was carried to Moscow, where he was executed in 1613.

**DEME'TRIUS I., POLIORCETES**, King of Macedonia, son of Antigonus and Stratonice. At the age of 22, his father sent him against Ptolemy, who had invaded Syria. He was totally defeated near Gaza, but soon repaired the misfortune by a victory over Cillex. After other various successes, he led a fleet of 250 ships to Athens, and freed the people from the power of Cassander and Ptolemy, some time afterwards defeating Cassander at Thermopylae. In the next campaign, he completely destroyed Ptolemy's naval power. In 301 B.C., he was defeated at Ipsus, and the fickle Athenians, who had worshiped him as a god, now deserted and reviled him. The loss of his possessions in Asia recalled him from Greece, and he established himself on the throne of Macedonia by the murder of Alexander, the son of Cassander, 294 B.C. Afterwards he had a stormy reign, and was finally forsaken in battle by his troops and made a prisoner, dying in confinement.

**DEME'TRIUS II.**, grandson of Demetrius Poliorcetes; king of Macedonia for ten years. Little is known of his reign. He offered a slight opposition to the two patriotic leagues, and wrested Boeotia from the Ætolians. He died 232 B.C.

**DEME'TRIUS I., SOTER**, King of Syria; sent to Rome as a hostage during the reign of Antiochus Epiphanes. He escaped from confinement, and established himself on the throne. He fell in battle against the usurper Balas about 150 B.C.

**DEME'TRIUS II., NICATOR**, son of Demetrius Soter, lived many years in exile, but with the assistance of Ptolemy Philometer, whose daughter he married, he regained the throne of Syria. He was soon expelled for cruelty and vices; and Antiochus, infant son of Alexander Balas, was made king instead. After ten years of captivity, Demetrius once more regained the throne; but his wife Cleopatra, indignant at his subsequent marriage with a daughter of the king of Parthia, caused him to be assassinated, 126 B.C.

**DEME'TRIUS III., EUCERUS**, called also Eugertes, and Philometer; king of Syria. He recovered a part of his Syrian dominions, and held his court at Damascus. He assisted the Jews against Alexander Jannæus. In attempting to dethrone his brother Philip he was defeated by the Arabs and Parthians, and taken prisoner. Mithridates, king of Parthia, kept him in confinement until his death.

**DEME'TRIUS**, a sculptor of Attica, supposed to have flourished about 440 B.C. He was so close an imitator of nature that he was censured for reproducing her imperfections.

**DEME'TRIUS OF BYZANTIUM**, a peripatetic philosopher, supposed to have been the man who dissuaded Cato from suicide. Some portions of his writings are said to have been found at Herculaneum.

**DEME'TRIUS OF SUNIUM**, a cynic philosopher, disciple and afterwards antagonist of Apollonius of Tyana. Caligula, being desirous of counting a philosopher among his sycophants, sent a large bribe to Demetrius, who refused it, saying, "if Caligula wishes to bribe me let him send me his crown." Vespasian banished him because of his bitter speech. Seneca observes that nature made him to show mankind how an exalted genius may live uncorrupted by the vices of the world.

**DEME'TRIUS, PHALE'REUS**, so named from the Attic demos of Phalerus, a seaport of Athens, where he was born about 345 B.C., was distinguished as an orator and politician. Though descended from a family possessing neither rank nor property, yet by the resolute and persevering exercise of his abilities, he rose to the highest honors at Athens. Having been educated in the school of Theophrastus, he entered upon public life about 325 B.C., and soon made himself famous by the display of great oratorical talent. In 317 B.C., D. was placed by Cassander at the head of the administration of Athens, which office he discharged with such acceptance for nearly ten years, that the grateful Athenians, during that time, heaped all kinds of honors upon him, and erected to him no less than 360 statues. During the later period of his administration, he seems to have given himself up to dissipation; and when Demetrius Poliorcetes, king of Macedonia, approached Athens with a besieging army, in 307 B.C., D., having lost the sympathies and co-operation of the Athenians, was obliged to flee. All his statues were demolished except one. D. retired first to Thebes, but afterwards found refuge in the court of Ptolemy Lagi, at Alexandria, where he lived for many years, devoting himself to literary pursuits. On the death of his protector, D. was expelled from the court of Egypt, and retreating to Busiris in Upper Egypt, he is said to have died there from the bite of an asp, 283 B.C. D. was the last of the Attic orators worthy of the name. His style was graceful, insinuating, and elegant; bearing, however, in its luxuriousness and tendency to effeminacy, the marks of a declining oratory. The list of his works (50 in number) given by Diogenes Laërtius shows him to have been a man of most extensive acquirements.

**DE'MI**, or **DE'MY** (half). In heraldry, an animal is said to be demi when only the upper or fore half of it is represented. In inanimate objects, the dexter half per pale

is usually intended, when it is said to be demi, though a *demi-fleur-de-lis*, for example, may be a *fleur-de-lis* divided per fess.

**DEMI-BASTION**, in fortification, is a kind of half-bastion which frequently terminates the branches of a crown-work or horn-work, and which is also occasionally used in other places. See **BASTION**, **CROWN-WORK**, **HORN-WORK**.

**DEMIDOFF**, a Russian family who in Russia occupy a position as capitalists similar to that held by the Rothschilds elsewhere, and who are not more celebrated for their wealth than they are for their beneficence.—**NIKITA D.**, the founder of the family, was a serf in the time of Peter the great, but, leaving the place of his birth in order to escape being taken as a recruit, he afterwards became famous as a manufacturer of arms, and before his death, had amassed an immense fortune. In 1699, he established an iron-foundry, under the auspices of Peter the great, in whose favor he had attained a high position, near Neviansk, on the eastern base of the Ural mountains; this being the first iron-foundry ever established in Siberia. He subsequently erected numerous other forges among the solitudes of the Urals, and realized from them very great riches.—**AKIM D.**, son of the preceding, employed German workmen to explore the rich mines of gold, silver, and copper, that are found in the valley of the Irtysh, and the upper reaches of the Obi. In 1725, he built, at the foot of the Magnetic mountain, in Siberia, a foundry called Nischneitagilsk, which is still the most important in all Siberia. The Russian government, sensible of the great service done to the country by the labors of such a man, conferred upon the enterprising metallurgist the title of counselor of state.—His son, **PROCOPE**, founded in 1772 a school of commerce at Moscow, intended to furnish a complete education for the sons of Russian tradesmen. This establishment was transferred to St. Petersburg in 1800.—**PAUL D.**, cousin of Procope, also a man of energy, traveled extensively when young, devoting himself to the cultivation of the natural sciences. He presented to the university of Moscow a valuable museum of natural history, and founded also, in 1803, the Demidoff museum, at Yaroslavl.—**NICHOLAS**, count D., nephew of the preceding, b. in 1774, distinguished himself while young as an aide-de-camp in the war against the Turks. Later, he married the countess Stroganoff, and became a privy counselor and imperial chamberlain. His taste for the fine arts and for the natural sciences led him to travel extensively; he also caused the workmen whom he employed in his mines to travel, in order to acquaint themselves with the processes of foreign miners. In 1812, he fought at the head of a regiment which he himself raised and led against the French. His death occurred in 1828. A collection of his works, entitled *Opuscules d'Economie Politique et Privée*, was published at Paris in 1830. Of his two children, Paul and Anatol, the former died young, leaving the great bulk of his fortune to the latter, who was b. in 1810 or 1812, and was educated in France. He was always remarkable for his enthusiasm in letters and in the sciences. His principal book, published at Paris in 1839, and of which an English translation appeared at London in 1853, is entitled *Travels in Southern Russia and the Crimea, through Hungary, Wallachia, and Moldavia*. D., in 1840, married the princess Mathilde de Montfort, daughter of prince Jerome Bonaparte. After five years, the marriage, by which there had been no children, was by mutual consent dissolved. D., on the 19th June, 1856, presented the town of Spa with a bust of Peter the great. Russia, as well as other countries, owes the foundation of many valuable charitable institutions to the philanthropy of Demidoff. D. died at Baden, 13th July, 1858.

**DEMI-GORGE**. See **BASTION**, **GORGE**.

**DEMI-LUNE**, in fortification, is a work constructed to cover or defend the curtain or wall of a place, and the shoulders of the adjoining bastions. It is composed of two-faces, forming a salient angle towards the open country outside the place. It has two demi-gorges, formed near the counterscarp, and is surrounded by a ditch. See further under **LUNETTE** and **RAVELIN**.

**DEMI-MONDE**, the better class of courtesans in Paris and other cities, including a class whose reputation is a little above these, and yet not good enough to warrant their reception in strictly moral society. They are noticeable from the fact that the leaders among them have been for years the dictators of the fashions for women's dresses in Europe and America.

**DEMING**, **HENRY C.**, 1815-72; b. Conn.; graduate of Yale, and of Harvard law-school; a lawyer and politician, who held a number of state offices. He served in the union army during the rebellion as a colonel of the 12th Connecticut volunteers, and mayor of New Orleans. In 1864, he was a member of congress from Connecticut.

**DEMIR-HISSAR** ("iron-castle"), a t. of European Turkey, in the province of Saloniki, in lat. 41° 12' n., long. 23° 28' east. It is situated on a tributary of the Karasu, at the foot of an old fort-crowned hill, is fortified, and contains several mosques and a Greek church. Pop. 8,000.

**DEMISE**. See **LEASE** (ENGLISH).

**DEMISE OF THE CROWN**. That "the king never dies," is a maxim of the public law of this country, in accordance with which, immediately on the death of the reigning

monarch, the sovereignty passes to his successor, by the act of the law itself. No installation, proclamation, coronation, or other ceremony is required to vest the new sovereign in the regal office, and thus there is no interval or interregnum, and the royal dignity remains perpetual. The word *demise* has, in English law, the more general signification of a lease or conveyance, by which a man grants lands or tenements to another for life, for years, or at will; such estate being short of the lessor's own interest therein. It is thus, as it were, by a sort of courteous and royal analogy that it is employed to signify the death of the sovereign. "So tender," says Blackstone, "is the law of supposing even a possibility of his death, that his natural dissolution is generally called his demise, an expression which signifies merely a transfer of property."

**DEMI-SEMI-QUAVER**, half a semi-quaver, or the 32d part of a semi-breve. See NOTATION.

**DEMIURGE** (from Gr. *demos*, people, and *ergon*, a work; hence a handicraftsman) was the name given in the cosmogony of the Gnostics to the creator or former of the world of sense. He was conceived as the archon or chief of the lowest order of the spirits or eons of the pleroma; mingling with chaos, he formed in it a corporeal animated world. He created man, but could impart to him only his own weak principle, the *psyche* or sensuous soul; therefore the highest, the really good God, added the divine rational soul, or *pneuma*. But the power of evil in the material body, and the hostile influence of the merely sensuous demiurge, prevented the development of that higher element. The demiurge holding himself to be the highest God, could not bring his creatures to the knowledge of the true Godhead; as the Jehovah of the Jews, he gave them the imperfect law of Moses, which promised merely a sensuous happiness, and even that not attainable; and against the spirits of the *hyle*, or world of matter, he sent only a psychical, and therefore powerless Messiah, the man Jesus. See Gnostics.

**DEMMIN'**, a t. of Prussia, on the river Peene, on the borders of the Pomerania and Mecklenburg, in lat. 53° 50' n., long. 13° 1' east. Besides the town proper, D. comprises three suburbs. It has four public squares and a town-house, and manufactures of woollens, linens, hats, and leather. It has also distilleries and breweries, and some trade in tobacco, gloves, etc. Pop. '75, 9,856. D., which is a place of some antiquity, was a walled and fortified town during the 12th century. It suffered considerably during the thirty years' war, previous to which it was of much more importance than it has since been.

**DEMMIT**, a co. in s.w. Texas, on the Neuces; 1050 sq.m.; pop. '70, 109. Timber and water are plenty; stock-raising is the only business.

**DEMOCEDES**, b. 550 B.C.; a Greek physician. While on a visit to Sardis, he was seized by the Persians, and sent to the court of Darius, to whom he rendered such medical assistance that he was allowed to accompany a party of Persians on a secret mission to Greece. He managed to escape, or was rescued by his fellow-citizens. He married a daughter of the wrestler Nilo.

**DEMOCRACY** (Gr. the rule of the people). It is interesting to trace the progress of this idea, which now plays so important a part. In Greece, whence we derive the name, it was understood to mean a commonwealth so constituted that the power was exercised by the body of the citizens (the *demos*), and not by an individual, or by a dominant caste. Democracy, therefore, stood opposed both to monarchy and aristocracy. Most of the republics of Greece, more especially that of Athens, were democracies in this sense. The name by no means implied the notion of an absolutely equal right in all citizens, still less in all men, to the exercise of political power. Neither the total absence of rights of all kinds on the part of the larger half of the population, the slaves, nor the distinctions recognized by law among citizens proper (e.g., the exclusion of the poorer citizens from office under the Solonian constitution at Athens), were considered incompatible with the nature of a democracy; though in regard to inequalities among citizens, the continually growing force of the democratic principle tended to their gradual extinction, and the transference of power to the mass of citizens without distinction. Aristotle regarded this as an encroachment of *ochlocracy* (mobocracy), the degenerate form of democracy, or democracy proper. Or more frequently, he speaks of democracy as the degenerate form of the polity (Gr. *politeia*). The polity with him was the form where the many govern for the common benefit.—*Polit.* III. chap. 5, and IV. chap. 6.

In modern history, we meet at the very threshold a state of society which may be called democratic. Among the German nations, we find an almost perfect equality of all freemen (i.e., all that were not slaves), and real self-government exercised by these freemen in each separate tribe. For the personal distinction enjoyed by certain families gave them no privileges over the other freemen, and where royalty existed, it could hardly be said to rule, since the king could do nothing without the concurrence of the assembly of freemen, and reigned not by mere birthright, but required the confirmatory choice of the people.

This condition of general liberty and equality gave place gradually to one of a quite opposite kind. Through the growth of the feudal system (q.v.), the majority fell into a more or less abject dependence upon a privileged minority. The mass of former

freemen, now sunk into serfdom, were hardly distinguishable from those properly slaves, whose position, on the contrary, was become less dependent. The dominant class, the nobility, branded all that did not belong to themselves as "people," "commonalty," "canaille." Thus the term "people," which in the ancient republics implied the rights of citizenship, came to denote the masses that were without rights. The distinction between the dominant class and the mass of the people rested chiefly on two points—exclusive occupation in war, and the free possession of land, which was granted for warlike service alone.

But within this system of graduated dependence, from the monarch down through the aristocracy and their retainers in various degrees, there sprang up slowly an opposing element, which, as originating in the mass called the people, we may designate as democratic. It was not so much a new element, as the resuscitation of the old Roman municipal life, which had never altogether become extinct. It was of course in the cities that this fresh element first manifested itself. Here, instead of a lord with a group of dependents, there arose communities of men with equal rights and self-government. At the same time, a new material interest, that of movable property, the product of industry and commerce, began to claim recognition alongside of territorial possessions and nobility. In England, as early as the Anglo-Saxon times, a merchant who had made three voyages ranked with a thane; and soon after the Norman conquest, the cities were represented in parliament on an equal footing with the warlike aristocracy. This took place later on the continent, and never to the same extent, except in the cities of Lombardy and Flanders, where, at an early period, the citizen element entered the lists with the feudal and warlike. Even within the cities, the same contest was carried on between aristocracy and democracy. At first, it was only those carrying on commerce on a large scale that asserted their right to take part in the municipal government of the towns; but the trades or guilds soon set up the same claims. These claims were pertinaciously prosecuted, and often led to bloody contests, but sooner or later were everywhere victorious. Thus was the basis of democracy widened; although the guilds also did not fail to manifest an aristocratic and exclusive spirit towards the body of the people not belonging to them, and with their restrictions and monopolies acted oppressively to the country population. It was not so easy for these last to break the bonds of feudal subjection in which they were held, or to acquire any political standing. Isolated attempts to throw off the yoke, by peasant insurrections and wars, failed, and only were followed by increased oppression. The abrupt division between the feudal possessor of the soil and the serfs under him continued long everywhere except in England. There the rigor of the relation began early to give way, and the transition was effected in such a peaceable and gradual way, that the English historian cannot say exactly how or when. For the greater part of the continent, it was not till the French revolution in 1789, and the impulse given by it to legislation in other countries, that the agricultural population acquired more or less complete freedom and equality with other classes.

Thus had one part after another of that "people," so oppressed and contemptuously thrown into the background by the dominant class in the middle ages, emerged from bondage, and successfully asserted a participation of rights that were at one time the privileges of a single class. The aristocratic principle of feudal society, the principle of exclusion, privilege, of the subjection of the majority to a minority, had given way to the democratic principle of the equal rights of all classes, of all callings and employments. But the development of this last principle was not yet complete. Those who had made good a position in the state alongside of the feudal aristocracy, formed in their turn an exclusive class, taking their stand on certain material grounds. Thus, the merchants, as representing large masses of capital; the guilds, with their privileged industry; the agriculturists, as possessors of land, however little: all these interests formed, as it were, another aristocracy within the democracy. They were democratic in their origin, and as compared with the class that was at one time exclusively privileged; but in another point of view they were aristocratic, since there still remained without a numerous body, which, instead of elevating to political power with them, they rather repelled, and treated much as the nobility had treated themselves. This residuary mass, which now came to be chiefly designated by the name "people," comprehended all those who possessed no capital, no privileged trade or calling, no land—nothing, in short, but their personal powers and capacities for work. This class forms at the present day by far the most numerous portion of the population in nearly all the civilized states of Europe. The designation "people," intended to be depreciative, is taken by them in the very opposite sense, and they ground upon it their claim to rule the state, as being properly the people, the numerically strongest class of the community. The preference given to the class of possessors, they look upon as groundless and absurd, just as these had judged of the nobility; they therefore claim perfect equality with them, especially in the exercise of the highest political rights. It is from this point of view that universal suffrage and the rule of mere numbers, without regard to possessions or other conditions, has been proclaimed as a self-evident consequence of the democratic principle.

With this there is connected in many quarters a still further extension of the idea. The same principles, it is said, that have dictated political reformations, call for a

remodeling of the social arrangements of mankind; that the possessors of property, the *bourgeoisie*, ought to be deprived, not only of the political privileges they have hitherto enjoyed, but also wholly or in part of the material basis of those privileges, their property, so as to produce a perfect equality, political, material, and social, of all classes. This gives rise to a division of the democrats of the present day into two parties: the purely democratic party, aiming only at securing the political consequences of the democratic principle—universal suffrage, and the absolute equality of social rights; and the “democratic and social,” who look upon the attainment of political rights as only a means of ultimately securing the general social equality of men.

There seems, however, to be a fundamental error in thus treating the relation between the possessionless class and the possessors as analogous to that between the serfs and lords of feudalism. The contest of democracy against feudalism was not primarily so much for equal rights as for this, that among the same people mere birth should not make one man privileged, and a ruler; another destitute of all rights, and bound to obey. It was a contest for personal freedom, the right for every man to use his powers for his own behoof, and not for that of a master; the right to the free possession of land, etc. Participation in political rights was chiefly prized as a guarantee for securing this personal and social liberty. Now, there is no such absolute distinction between possessors of property and non-possessors, as between the nobleman and *roturier* of the middle ages; the two classes run imperceptibly into one another. Still less does the one class exercise any right of controlling the personal freedom of the other in respect of labor and acquisition, as was the case in villenage and feudal servitude. Possession has endless gradations, and in the present day, he who had nothing at the outset often becomes a capitalist, and the reverse. There may be other reasons for wishing that there were less abrupt differences of possession, and greater social equality between the lower and middle classes than society actually presents (see SOCIALISM); but this by no means follow, necessarily from the notion of democratic equality. All that this notion requires, seems to be the removal of all privileges that destroy the unity and homogeneity of a nation, the establishment of complete personal and social liberty, and of the equality of all in the eye of the laws; and, in regard to political rights, or direct participation in the government of the state, such a form of constitution as will exclude no fixed class of citizens as such. All this, however, seems quite compatible with making the exercise of the different political functions dependent, in the case of each individual, on certain guarantees, and not admitting the whole body of the people to share in the government of the commonwealth at once, but only in proportion as increasing culture renders a wider circle capable of such functions. If we may judge from the example of England and Belgium, this is the way in which the real and steady progress of the democratic principle is best secured.

In France, the feudal principle, instead of a timely compromise with the democratic, as in England, came to a struggle with it of life and death. The consequence was that victorious democracy, instead of seeking to satisfy the practical wants of society first, and leaving the theoretical to be attained gradually, undertook to reorganize at one stroke the whole political and social fabric. In Germany, things took lately a similar course. The case of America is peculiar. There the foundation of the state structure was to be laid on a clear site, and the first page of the history to be written. Those who came together to form the new community were personally perfectly free and equal, and the local circumstances were such as to favor the exercise of this liberty and equality, by rendering any very great disparity in material means impossible. In such circumstances, the construction of a perfectly democratic order of society could be carried out without struggle, and without any dangerous straining of the principle. There no one looks upon the restriction of the franchise to residents—which is the law in most states of the union—as an infringement of the democratic principle. Norway bears no little resemblance to America; in that country, the democratic element was never so completely crushed as in other parts of the continent, and that form of society is favored by the means and style of living, which are extremely simple, and are based on a nearly equal division of the soil.

In the development of democracy in modern times, circumstances have directed its attacks rather against the aristocratic, than against the monarchical principle. At one time, monarchy, in its struggle with the aristocracy, found its natural allies in the democracy. The princes, in striving to break the power of the great nobles, which limited their own, often called in the help of the democratic element, partly by conferring privileges on bodies of the people, such as city corporations, and partly by attaching individuals of the non-privileged classes to their personal service, and appointing them to influential positions in the state. The road to power and distinction was, it is true, already open to individuals of the democracy through the church, whose dignities and privileges were not confined to the noble by birth, but were accessible to personal capacity. At a later period, the universities, especially in the faculty of law, formed for the democracy stepping-stones to power, from which they sometimes overtopped the aristocracy of birth. And when the princes—at their head the Louis of France—aiming at absolute authority, sought to find a counterpoise to the feudal nobility, by creating a bureaucratic state machinery, and favoring intelligence in every form, the very widest path was opened to the democratic element for attaining influence and distinction. It is true that all this

was at the cost of its most essential principle; for the equality created by a leveling absolutism, raising the low and depressing the high, was nothing more than an equality of dependence upon the one absolute master of all.

The relation between democracy and monarchy was different where the ruler came to be limited as the chief officer of the nation. Such a limitation of the power of the monarch, by means of a representative system not confined to the privileged classes, but embracing at least the citizens of towns, was in itself a victory of the democratic principle. As the circle of this popular representation widens, and its influence in the state increases, such a monarchy becomes more and more democratic in all its institutions.

In a purely democratical state, the people may exercise their power in either of two ways—directly, or through delegates: in the one case, the democracy is said to be absolute; in the other, representative. The absolute or direct form prevailed in the republics of antiquity; political representation, in fact, seems to be a modern idea. The same is the case with the original Swiss cantons, where almost all public business is discussed in a full assembly of the people. In Switzerland generally, the representative form is now preferred. It is also carried out in the states of North America, and was adopted in the French republic of 1848. The absolute form, in fact, is only adapted for small communities with a population concentrated as to space, and differing little in mode of life or culture. According to some, the representative system is inconsistent with the principle of democracy, as the will of the people is liable to be falsified and crossed by the very organs that are to carry it into execution. It is rather an advantage, however, that the first impulse of the public will, sometimes passionate and short-sighted, should be tempered and enlightened, by passing through a series of media on its way to action; and the hold which the constituency have upon their representatives, by means of frequent re-election, and in other ways, is sufficient guard against any defeat of a steady, earnest, public conviction.

M. de Tocqueville and Mr. J. S. Mill applied themselves to setting forth the evils and dangers of democracy, which they—the latter especially—both regarded not only as a system that must inevitably extend itself, but as the ideally perfect form of government. Mr. Mill was at great pains to show that self-government by a representative democracy is what develops, in the greatest degree, the good mental qualities, both intellectual and moral, of the governed, and that it is desirable gradually to extend this participation in the acts of government till it include the entire adult population, male and female. On the other hand, there are two sources of evil to which we are liable, more or less, as democracy approaches the term of universal suffrage, and which are to be provided against by proper constitutional arrangements. The first of these is the insufficient mental qualifications of the governing body for the highly complicated work of government. Public administration is a profession, like engineering, medicine, or the law, and demands, no less than these, a special training and devotion of mind. In monarchies and aristocracies, the management of affairs is in the hands of a few, who make it the business of their life, and acquire the requisite skill for doing the work well. In a democracy, this advantage is lost, except in so far as the details of administration are left to skilled officials: the public assembly merely retaining the power of checking and controlling those officials, and of determining general rules of policy.

The other danger is the predominance of the laboring class, by virtue of their numbers, over the class made up of employers of labor, and the rich and educated generally. When there are two or more classes in the community with conflicting interests, the desirable arrangement is, that their power should be equally balanced, so that no party could carry a point by political position alone, or without appealing to the reason, and sense of justice, of some members of the other parties. But if the suffrage were universal, the laboring-class interest would be the predominant one; and so serious would be the danger of class legislation as a result, that Mr. Mill thought it necessary to provide a remedy in the shape of granting a plurality of votes to certain persons, especially those distinguished by education, so as to restore the balance.—*Considerations on Representative Government*, chap. viii.

**DEMOCRACY** (*ante*). The definition of this term most widely accepted in the United States is embodied in the striking words of Abraham Lincoln: "A government of the people, by the people, for the people." This definition is fluctuating on account of the uncertain meaning of the word "people," which is generally used in a more or less restricted sense. Strictly speaking, it might be held to include every person in the jurisdiction, without distinction of age, sex, or class; but as a political term it is usually taken to mean only the great body of adult male citizens. In the days of slavery, by a mental reservation, negroes were generally excepted. Women and children, as well as idiots and criminals, are also excluded; but it is now insisted by a strong and growing party that the exclusion of women cannot be reconciled with the rational and consistent interpretation of the word democracy. The rights of this class are already so far recognized in some of the states that they are allowed to participate in the election of school officers, and to serve on school committees and boards of charity. The tendency of the times is undoubtedly towards a broader interpretation of the democratic idea, though the movement in this direction meets with a stubborn resistance. The government of the United States is called democratic, as also are the governments of the states com-

posing the union; but they are only comparatively, not purely such. See SUFFRAGE, *ante*.

**DEMOCRITUS**, an illustrious Greek philosopher, was b. at Abdera, in Thrace, about 470 or 460 B.C. Of his life, little is known. The statement that he was first inspired with a desire for philosophic knowledge by certain Magi and Chaldeans whom Xerxes had left at Abdera, on his Grecian expedition, is as untrustworthy as that which represents him as continually laughing at the follies of mankind. His extensive travels, however, through a great portion of the east, prove the reality of this desire, as does also his ceaseless industry in collecting the works of other philosophers. D. was by far the most learned thinker of his age. He had also a high reputation for moral worth. He appears to have left a strong impression of his disinterestedness, modesty, and simplicity on the mind of the community, for even Timon the scoffer, who spared no one else, praised him. The period of his death is uncertain. He lived, however, to a great age. Only a few fragments of his numerous physical, mathematical, ethical, and musical works are extant. These have been collected by Mullach (Berlin, 1843). Cicero praises his style, and Pyrrhon imitated it.

D.'s system of philosophy is known as the *atomic system*. Its essence consists in the attempt to explain the different phenomena of nature—not like the earlier Ionic philosophers, by maintaining that the original characteristics of matter were *qualitative*, but that they were *quantitative*. He assumes, therefore, as the ultimate elementary ground of nature, an infinite multitude of indivisible corporeal particles, *atoms* (see *ATOM*), and attributes to these a primary motion derived from no higher principle. This motion brings the atoms into contact with each other, and from the multitudinous combinations that they form, springs that vast and varying aggregate called *nature*, which is presented to our eyes. D. did not acknowledge the presence of *design* in nature, but he admitted that of *law*. "The word *chance*," he says, "is only an expression of human ignorance." He believed strictly in secondary or physical causes, but not in a primary immaterial cause. Life, consciousness, thought, were, according to him, derived from the finest atoms; those images of the sensuous phenomena surrounding us, which we call mental representations, were, according to him, only material impressions, caused by the more delicate atoms streaming through the pores of our organs. D. boldly applied his theory to the gods themselves, whom he affirmed to be aggregates of atoms, only mightier and more powerful than men. Strange to say, the ethical system of D.—in spite of the grossness of his metaphysics—is both pure and noble. Such fragments of his writings as we possess contain beautiful, vigorous, and true thoughts concerning veracity, justice, law, order, the duties of rulers, etc.; while, in a spirit not alien to the teaching of Christianity, he looks upon an inward peace of heart and conscience as the highest good, the end and the aim of all virtuous endeavor.

**DEMODOCUS**, a famous singer, who is represented by Homer as celebrating at the banquet of Alcinoüs the Greek heroes of the Trojan war. He also sang the loves of Venus and Mars. Some writers have represented him as a blind poet and musician of Corcyra.

**DEMOGORGON**, a mysterious and terrible being, referred to by the classical and mediæval writers, and in later poetry. He is to be the conqueror of Jupiter, and the ancients avoided even the mention of his name.

**DEMOISELLE**, *Anthropoides*, a genus of birds of the family *gruidæ* (cranes), differing from the true cranes in having the head and neck quite feathered, and the *tertials* of the wings elongated and hanging over the tail, so as in some species to reach the ground. The D., or *NUMIDIAN D.* (*A. virgo*), is about 3 ft. in length from the point of the bill to the tip of the tail, and the top of its head is about 3½ ft. from the ground. It is remarkable, as are all its congeners, for elegance and symmetry of form, and grace of deportment. The general color of its plumage is gray, but the sides of the head are adorned with two elegant white tufts, formed by elongation of the ear-coverts, and a tuft of blackish feathers hangs down from the breast. The D. is an African bird, but visits Greece and other parts of the s. of Europe. To the same genus belongs the beautiful Stanley crane (*A. paradiseus*) of the East Indies, a larger and taller bird, with very long tertials. Notwithstanding its large size, it seems to feed chiefly on the insects of marshes, which it takes when on wing.

**DEMOIVRE**, ABRAHAM, a distinguished mathematician, was b. at Vitri, in Champagne, 1667, and died at London in 1754. Of French extraction, he spent most of his life in England, whether he fled, with many others, for shelter in 1685, on the revocation of the edict of Nantes. He long supported himself by private tuition and public lecturing, and, towards the end of his life, by answering questions in chances, play, and annuities, most of his responses, it is said, being given at a coffee-house in St. Martin's lane, where he passed much of his time. The appearance of Newton's *Principia* incited him to increased devotion to mathematical studies, to which he had always been disposed, and at last he ranked among the leading mathematicians of his time. He was a member of the royal societies of London, Berlin, and Paris. The *Philosophical Transactions* of London are enriched by many contributions from his pen; and he was so esteemed by the royal society, that they judged him a fit person to decide the famous

contest between Newton and Leibnitz for the merit of the invention of fluxions. Among his published works are *Miscellanea Analytica de Seriebus et Quadratis*, etc. (1730, 4to); a work on *The Doctrine of Chances* (1718 and 1738), dedicated to sir Isaac Newton; and another on *Life Annuities* (3d edit., 1750). D.'s name is well known from its association with a useful trigonometrical formula—viz., that whatever be the index  $n$ ,  $\cos n\theta + \sqrt{-1} \sin n\theta$  is a value of  $(\cos \theta + \sqrt{-1} \sin \theta)^n$ .

**DEMOLITION**, in military operations, is one of the destructive parts of the duty intrusted to the engineers. When works and buildings belonging to the enemy are to be destroyed, to facilitate operations on the one side, or to obstruct on the other, rules are laid down by which the demolition may be most easily and quickly effected. The quantity of gunpowder to be blasted for bringing down masonry of a particular thickness, the determination of the line of least resistance—these and similar matters are required to be studied by officers of the engineer corps.

**DEMOTAX**, a cynic philosopher of Athens, of the 2d c. A.D. He was a native of Cyprus, highly honored while living, and at death publicly buried with great magnificence.

**DEMONIACS** (*demoniaci*, *obsessi*, or, with reference to the supposed influence of the moon, *lunatici*), the name given by the Jews to persons afflicted with epilepsy, hypochondria, or insanity, diseases of frequent occurrence in the east. The name originated in the belief, that persons so afflicted had been taken possession of by evil spirits or demons (q.v.). It was a prevalent opinion among the Persians, Greeks, Romans, and the ancients generally, that the extraordinary conditions and actions of men, which could not be referred to the known and apparent operations and powers of the mind, must be ascribed to the influence of one or more higher spirits. This belief is found in Homer, Herodotus, Euripides, and later writers, and also rooted itself very deeply in the Christian mind during the middle ages. As the *good*, when beyond the limits of the ordinary powers or faculties of great men, was attributed to the inspiration of the Muses, or to the direct co-operation, or even incarnation in their persons of some beneficent deity, so also that deep internal unhappiness of "a mind diseased," which no strength of will, and no physician's art in olden times could remove, was as unhesitatingly attributed to evil spirits, or *demons*, as the later Jews, probably with an oblique reference to paganism, called them. Spells and exorcisms, in consequence, took the place of the healing art in reference to such as were supposed to be demonized, and the Jewish exorcists (demon-banishers) alleged, according to Josephus, that they possessed the necessary magic formulas, wonder-working roots, etc., which had been handed down from antiquity. The good spirits thus appeared—in harmony with the idea that healing was a thing natural and divine in itself, the normal action, so to speak, of nature—to fulfill their function in banishing and destroying the demons. Thus, Christ appears in the synoptic gospels as healing many who were possessed of unclean spirits, casting out devils, etc. But apart from the fact, that a belief in demoniacal possession was more vital and universal among the later Jews than among the other nations, on account of their being more deeply penetrated by the consciousness of sin, and by a conviction of the mysterious connection between evil and Satan, it was also expected of the Messiah, the anointed of God, that he would possess "power" over demons. This fundamental national belief would unconsciously prepare the contemporaries of Christ for regarding his divine exercise of the physician's art from a *religious* rather than a *scientific* point of view. When they beheld the miraculous effects of his "power" on the bodies and spirits of the so-called demoniacs, it was natural that they should speak of it in language intelligible to their age, and in harmony with its general notions. To have used other words from the stand-point of a higher scientific knowledge, would have been as confusing to the Jews and earliest Christians as it would have been to assure them that it was the *earth*, and not the *sun*, which stood still during the battle at Gibeon. Besides, when it is remembered that before even the synoptic gospels were written, the miraculous incidents in Christ's life must have fixed themselves in the memory of the populace, under the conditions of the popular belief, it is difficult to see that there was any other course open to the evangelical historians, even if they did not share the common belief of their countrymen, than to adopt the current representations. They had no interest in the mere scientific accuracy or inaccuracy of such representations. Their object was different and higher: it was to show the power, wisdom, and goodness of the Saviour, qualities which are equally manifest whichever theory may be adopted. This view of the question, which is held to be in conformity with sound science and sound criticism, presents itself almost irresistibly to the candid and impartial student of the Bible, when he bears in mind that there is nothing in the recorded examples of demoniacal possession different from the ordinary symptoms of epilepsy, hypochondria, and insanity, which are not *now* beyond the physician's skill.

**DEMONS** (Gr. *daimōnes*, Lat. *genii*) are, according to superstitious belief, spirits which exercise an influence on the fortunes of men. Their dignity and character have both changed greatly in the course of time. Homer calls the *gods* demons, and *daimoniakos* is with him equivalent to *divine*. Hesiod affirms that there are in the air 30,000 D. or ministering spirits, who were the souls of men in the golden age; but a proper classification of these is first found in the Pythagorean and Neo-Platonic systems. Aristotle

separates the immortals into gods and D.; mortals, into heroes and men. Plato, from whom Aristotle probably received the hint of his division, says in his *Symposium* that "the demon is a middle intelligence between God and man, and the uniting link which completes the chain of being." In other places, he informs us that they inhabit the air, wander through the sky, hover over the stars, and tarry on the earth. They also see the hidden issues of the future, and can alter them at their pleasure. Every mortal receives at his birth a particular demon, who accompanies him to the end of his life, and bears his soul to the place of purification and punishment. In general, it may be said that the Greeks included the divinity or Deity among the D., in so far as he arranged and disposed the dissimilar fortunes of men. In reference to the actions ascribed to them, the D. were divided into *good* and *bad*—*agathodaimones* and *kakodaimones*. These evil D. were not, however, originally supposed to be hostile to the divinity or supreme demon. They came from him, and carried out his purpose as truly as the good demons. This was precisely the belief of the earlier Jews also, as we find, for example, from the history of Saul, into whom God repeatedly sent an "evil spirit," i.e., a demon, in the classical and not in the mediæval sense of the term. The demonism of the Romans consisted chiefly in the worship of departed spirits. See LARES, MANES, and PENATES. The origin of the doctrine of D. is to be sought for in the east. In the teaching of the Hindus, who, besides the highest Deity, Brahma, recognize a countless number of divine agents or messengers, the D. are called *deities*. In Parseeism, or the religion of Zoroaster, however, this doctrine is found in its most systematic and elaborate development. Indeed, the Persians and Jews *alone* among the nations of the old world had the conception of evil spirits headed by a chief demon, a Satan, who was over them as a god. To the genii or D. in the kingdom of Ormuzd (light), who are called *Izeds*, stand opposed the genii in the kingdom of Ahriman (darkness), who are called *Dews*. According to the belief of the Egyptians, the circuit of the world (the sea, the earth, the air) was filled with D., who ruled the elements, exercised mysterious influence over stones, metals, and plants, and had the souls of men in their power. Although demonism came to Greece from various countries, and by various channels, yet the principal source of it was Egypt. The Jews derived theirs—at least to a great extent—directly from the Persians, during the time of the Babylonish captivity; and although acquainted with "angels" from an early period, angelology, beyond all question, first received elaborate treatment after the return from exile. The dualism which characterizes the system of Zoroaster now made itself conspicuous here. According to the Jewish demonology, there were seven good D. who formed the council of Jehovah, and ever stood before his throne, while the evil D. have at their head Satan or Asmodi. After the Jews had, under the Seleucidæ and Ptolemies, entered into extensive commercial relations with the Egyptians and Greeks, especially in Alexandria, Græco-Egyptian conceptions were associated with those derived from Persia. When Christ made his appearance in the world, the Jewish conception of a demon as an "evil spirit," *not* from God, had become definitely fixed and popular. This narrowing of the application of the word may have partly originated in the wish to glorify Judaism at the expense of paganism. It would gratify the national pride, which was strongest when it had least to boast of, to include the D., i.e., the spirits both good and bad, of all the surrounding Greek-speaking nations, in one black category, and so make them stand as the representatives of evil. The early Christian writers carried out this tendency to perfection; for instead of denying the existence of the heathen gods, they turned them into D., who, acting under the inspiration of their wicked master, had cheated the souls of men, and so made them also worship Satan unawares. See DEVIL. The doctrine of the early church concerning the fall of the D., based on Genesis vi. 2, and concerning their activity, is a mixture of Jewish and Platonic notions, Christianized, however, by the belief that all their action is controlled and directed by God. Among the Germanic races, during the middle ages, the idea of a person's being taken possession of by D., led to the other idea of a covenant with the devil, of which the legend of Faust is a well-known example. See Ukert, *Ueber Dämonen Heroen und Genien* (Leip. 1850); and Conway's *Demonology and Devil Lore* (1878).

**DEMONSTRATION** (Lat. *demonstrare*, to point out, to cause to see), in mathematics, is a proof of any proposition which excludes doubt; such are the demonstrations of the propositions in Euclid's *Elements*. The method of demonstration in mathematics is the same with that of drawing conclusions from principles in logic, and is usually syllogistic, the premises being omitted to be stated at each turn. The principle of *reductio ad absurdum* is also employed. See REASONING, SYLLOGISM.

**DEMONSTRATION**, in military operations, is an apparent movement or maneuver, the chief object of which is to deceive the enemy, and induce him to divide his force, as if to meet dangers from various quarters. When thus divided and weakened, he may be attacked with greater chance of success.

**DEMONTÉ**, a t. in the s.w. of Piedmont, northern Italy, situated on the Stura, 15 m. s.w. of Coni. Pop. 6,078.

**DE MORGAN**, AUGUSTUS, was b. in 1806, in the small Indian island of Madura, on the n.e. coast of Java. His father was an officer in the British army. He was educated

at Trinity college, Cambridge, and took his degree of B.A. in 1827, when he was fourth wrangler. He was appointed first professor of mathematics in the University college, London, after its foundation in 1828. In 1831, he resigned this office, but was reappointed in 1836, and continued in that capacity till his death. His writings are very numerous. Besides being a mathematician of the first order, he was extensively and minutely versed in the history of the mathematical and physical sciences. He also devoted himself to the development of the Aristotelian or "formal" logic, to which he has given so symbolical a shape as to make it seem like a branch of algebra. He has written likewise on the calculation of insurances and on the decimal coinage. The following are the titles of a few of his works: *Elements of Arithmetic* (1830); *Elements of Algebra, preliminary to the Differential Calculus* (1835); *Elements of Trigonometry and Trigonometrical Analysis, preliminary to the Differential Calculus* (1837); *Essay on Probabilities, and on their Application to Life Contingencies and Insurance Offices* (1838); *Formal Logic, or the Calculus of Inference necessary and probable* (1847); *Arithmetical Books, from the Invention of Printing to the Present Time, being brief notices of a large number of works drawn up from actual inspection* (1847). De M. is also the author of the treatises on the differential and integral calculus, published by the society for the diffusion of useful knowledge; and contributed largely to the *Penny Cyclopædia*. He died Mar., 1871.

DEMOS, a name applied first to the 100, and afterwards to the 174 districts into which Attica was divided. They had each their own officers, assemblies, and religious usages.

DEMOSTHENES, the greatest orator of Greece, and indeed of the ancient world, was a native of Athens. The date of his birth is doubtful. Fynes Clinton assigns it to the year 382 B.C.; Thirlwall and other good authorities, to the year 385 B.C. His father, a wealthy manufacturer, died early, leaving his fortune and children to the care of three guardians, who cruelly abused their trust. As soon as D. came of age, he resolved to prosecute at law these unfaithful stewards. He gained his case, but much of the property had been already squandered, and he only recovered enough to save him from poverty. His success in this and some other civil causes fixed his resolution to devote himself to public life; and he set himself to master the law and politics of his country with a labor and perseverance almost without a parallel. His first care was to conquer the physical disadvantages under which he labored. His health was naturally feeble, his voice harsh and tuneless, and his action ungraceful. To strengthen his lungs, he used to climb steep hills, reciting as he went, or declaim on the shores of the sea in stormy weather. To improve his delivery, he took instructions from Satyrus the actor, and did not even disdain to study effects before a mirror. His feebleness of health he never fairly overcame, but he obviated the defects of his early training by the severest study pursued for months at a time without an interruption.

D. first began to take part in public affairs in the 106th Olympiad, when he was between 27 and 30 years of age, and from that time till his death, his history is the history of Athens. The states of Greece were at this time miserably weak and divided, and had recklessly shut their eyes to the dangerous encroachments which Philip of Macedon was even now making on their common liberties. The first period of D.'s public life (extending over ten years from 356 B.C.) was spent in warning his countrymen to abate their mutual jealousies, and unite their forces against the common enemy, whose crafty and grasping policy he exposed so nobly in 352 B.C. in the oration known as the First Philippic. Three years later, Philip became master of Olynthus, the last outpost of Athenian power in the north, which, in a series of splendid harangues—the three Olynthiacs—D. had implored his countrymen to defend. Peace was now necessary for Athens; and D. was among the ambassadors sent to negotiate with the conqueror; but Macedonian gold had done its work, and D., as incorruptible as he was eloquent, saw with despair that Philip was allowed to seize Thermopylæ, the key of Greece, and become a member of the Amphictyonic league. The peace lasted for six years, during which Philip's incessant intrigues were exposed and denounced by D. in orations hardly less remarkable for their political wisdom than for their matchless eloquence. The most important of these were the second, third, and fourth Philippics; and the speeches on the "Misconducted Embassy," and "The Affairs of the Chersonese." When war broke out in 340 B.C., D. introduced several important reforms into the army and navy, and showed such powers of vigorous administration, that Philip was baffled for a time. The struggle was closed in 338 B.C. by the battle of Chæroneia, which laid Greece prostrate at the feet of the Macedonians. Only once after that event did D. appear on the scene of his previous triumphs. But on that occasion he delivered, in defense of his friend Ctesiphon, his oration "For the Crown," which the almost unanimous verdict of critics has pronounced to be the most perfect masterpiece of oratory that ancient or modern times have seen. Æschines, his life-long enemy, against whom this speech was delivered, was so overwhelmed by it, that he quitted Athens, and spent the remainder of his life in exile. In 324 B.C., D. was accused of taking part in a revolt against the Macedonian domination, and thrown into prison, whence he escaped, and fled into exile. The death of Alexander the great in the following year brought a gleam of hope and sunshine to the Athenians; and D., recalled from exile, was again at the head of affairs. Once more the power of Macedon prevailed. D. was demanded up by the conquerors.

Finding escape impossible, the hunted orator sought an asylum in the temple of Neptune, in the island of Calauræa. Before his pursuers overtook him, he had died, as was generally believed, of poison administered by his own hand. His death took place in 322 B.C.

The personal character of D. is one which it is scarcely possible either to praise or to admire too much. His dauntless bravery, the stainless purity of his public and private life, his splendid and disinterested patriotism, and his services as a statesman and administrator, entitle him to a place among the highest and noblest men of antiquity. On his merits as an orator, it is hardly necessary to dwell. Suffice it to say, that the intelligent of all ages subsequent to his own have, with scarcely a dissenting voice, assigned to him the highest place. Homer is not more clearly the prince of ancient poets, than is D. the prince of ancient orators.—The best of the earlier editions of D. are those of Taylor and Reiske, both now superseded by the more recent edition of Bekker. His principal orations are translated into English by Leland, and the whole by Kennedy, in 5 vols., for Bohn's Classical Library.

**DEMOSTHENES**, a conspicuous Athenian gen. in the Peloponnesian war. He was one of the commanders sent, 413 B.C., to reinforce Nicias at Syracuse; but he was captured and put to death.

**DEMO TIC ALPHABET.** See **HIEROGLYPHICS**.

**DEMO TICA**, a t. of European Turkey, in the province of Roumelia, 22 m. s. of Adrianople. It is situated on the Maritza, here navigable for small vessels, and is defended by a citadal. Its contains an old palace, is the seat of a Greek bishop, and has manufactures of silks, woollens, and pottery. Pop. 8,000. Charles XII. of Sweden, who, after the battle of Pultowa, first found a refuge at Bender, afterwards removed to D., where he remained for some time.

**DEMPSTER, JOHN, D.D.**, 1794–1863; a Methodist clergyman, a native of New York. When young he was a peddler. At the age of 18 he was converted, and in 1816 he was admitted to the general conference, preaching in various places in New York and Canada. In 1835, he was a missionary to Buenos Ayres. In 1842, he had charge of a church in New York. In 1847, he founded the biblical institute which now constitutes the school of theology of Boston university. In 1856, he established a similar institution near Chicago. His *Lectures and Addresses* have been published.

**DEMPSTER, THOMAS**, a professor famous for his learning, and a miscellaneous and voluminous writer, was born at Muirresk, in Aberdeenshire, about the year 1859. What the rank or condition of his family was, is unknown; we know, however, that he studied at Cambridge, and that when he went to France, which he did while yet young, in order to perfect his education, he represented himself as a man of family, and as the possessor of an estate. At Paris, he obtained a professorship in the college of Beauvais, where he manifested a very quarrelsome temper, engaging, it is said, almost daily in some brawl. One of these unseemly disturbances resulted in D.'s having to retreat to England. To France, however, he again returned, bringing with him a wife, whom he had married while in England, and who was very beautiful. Crossing the Alps, he obtained a second professorship at Pisa, drawing a handsome salary for his labors. Here, however, the infidelities of his wife marred his peace; and he removed to Bologna, where he became professor of *belles-lettres*, and where his wife completed her shame by eloping with "one or more" of his students. Poor D. seems to have been fond of this wanton, for he took the trouble of attempting the capture of the fugitives. He failed; and died at Butri, near Bologna, 6th Sept., 1625.

D. is the author of numerous treatises, among which may be mentioned the *Historia Ecclesiastica Gentis Scotorum*—a work in which his desire to magnify the merits of his country often induced him to forge the names of persons and books that never existed, and to unscrupulously claim as Scotchmen, writers whose birthplace was doubtful, or who were known to be natives of England, Wales, Ireland, and even France and Germany; but nevertheless, in spite of its defects, it is justly reckoned a valuable and erudite performance. It was reprinted for the Bannatyne club in 1829.

**DEMULCENTS** (Lat. *demulceo*, I soften), bland and lubricating liquid substances, taken by the mouth, for the purpose of soothing irritation of the mucous membranes, and promoting the dilution of the blood, and the increase of the secretions. D. are chiefly composed of starch (q.v.), or gum (q.v.), or of substances containing these, dissolved in water; sometimes also of oily matters, or the white of eggs, and other albuminous or gelatinous substances largely diluted. The decoction of *althæa*, or marsh-mallow, is a favorite form of demulcent.

**DEMURRAGE**, in the law-merchant, is an allowance made to the master or owners of a ship, by the freighter, when she is detained in port by the latter beyond the specified time of sailing, for his own convenience. A certain number of days, called running or working days, are allowed for receiving and discharging cargo, and it is usually stipulated in charter-parties that the freighter may detain the vessel, either for a specified time, or as long as he pleases, on paying so much *per diem* for over-time. All the ordinary causes of detention, such as port-regulations, the crowded state of the harbor, and the like, are at the risk of the freighter, and D. must be paid, though it be

proved that the delay was inevitable by him (*Commentaries*, V. i. 431, Shaw's ed.). "In short," says Mr. Bell, "the rule is, that during the loading or unloading of the ship, the merchant runs all the risk of interruptions from necessary or accidental causes; while the ship-owners have the risk of all interruptions from the moment the loading or unloading is completed." But D. is not due where the delay arose from detention of the ship by a public enemy, or from hostile occupation of the port; and it cannot, of course, be claimed where the fault lay with the owners themselves, or the master, or crew of the vessel. The D. ceases as soon as the vessel is cleared for sailing, though she should be prevented from actually doing so by adverse winds. When the days of D. are limited by special contract, and the ship is detained beyond them, the sum due as D. under the contract will be taken as the measure of the loss for the further time which may be claimed in the form of damages. It will be open, however, to both parties to show, that the rate thus fixed *per diem* is either too high or too low. Where there is no stipulation beyond the ordinary agreement that the usual time shall be allowed for loading and unloading, the master will be entitled, when this period expires, either to sail or to claim damage for detention.

**DEMURRER**, in English law, is an exception by one party in a suit or action to the sufficiency in point of law of the case of the opposite party. At common law, each party might demur to the sufficiency of the pleading of the opposite party. The party whose pleading was demurred to might either amend or put in a joinder in demurrer. A demurrer in equity, like a D. in law, admitted the facts of the case, but stated objections to the form of the bill in equity (q.v.), or the sufficiency of the plaintiff's case to sustain the remedy craved. Since the judicature act of 1875, a D. is argued before a divisional court if in the queen's bench, common pleas, or exchequer division of the high court; before a single judge, if in the chancery division, or in the probate, divorce, and admiralty division.

*Demurrer to evidence* is also a form of procedure which existed in both common law and equity practice. In the former it had long been almost obsolete; and in its place was substituted a motion for a new trial (q.v.). It may arise on a trial at bar or at Nisi Prius (q.v.). It admits the facts proved, but objects that they are not sufficient to sustain the issue. In equity, a D. to evidence is where a witness refuses to answer a question put to him by direction of the court. The objection is then taken down in writing, and is argued before the judge by whom the interrogatories were settled.

*Demurrer to a criminal indictment* is also almost obsolete. After the passage of 7 Geo. IV. c. 64, this form of D., which was formerly of little moment, became of consequence to a prisoner, inasmuch as by neglecting to state in the form of a D. his objection to an indictment, he was precluded from afterwards insisting in them. But by 14 and 15 Vict. c. 100, it is enacted that no indictment shall for any of these defects be held insufficient; and further, that every objection for any formal defect in an indictment shall be taken before the jury is sworn, and may be amended by the judge. This last provision places demurrers in criminal cases on a similar footing to that of objections to the indictment in Scotland. There is, however, this material difference, that in Scotland the defect cannot be immediately remedied, but the prisoner, if the objection be sustained, undergoes a further detention in jail on a new indictment.

**DEMY**, a particular size of paper. In that of printing-paper, each sheet measures 22 inches by 17½; drawing-paper, 22 by 17; and writing paper, 22 by 15½.

**DENAIN**, a t. of France, in the department of Nord, on the left bank of the Scheldt, about 5 m. w. of Valenciennes. Its situation, in the center of an extensive coal-field, and in the immediate vicinity of iron mines, gives it unusual facilities for smelting iron, and its works of this kind are of considerable importance. D. is a regular and well-built town, and has a good market. It has some manufactures of beet-root sugar. Pop. 76, 11,849. Here the allies under lord Albemarle were defeated by the French under *maréchal de Villars*, 24th July, 1712.

**DENA RIUS** (*deni*, ten each), the principal silver coin among the Romans, was equal to ten *asses*, but upon the reduction of the *as*, the D. equaled sixteen of it. It was first coined 269 B.C. Its weight at the end of the Roman commonwealth is estimated at 60 grains, while under the empire the weight was 52.5 grains of silver. The value of the commonwealth D. was thus rather more than 8½d., and of the later period about 7½d.

**DENARY SCALE.** See NOTATION.

**DENBIGH**, a parliamentary and municipal borough, the county town of Denbighshire, in the n. of the county, 30 m. w. of Chester, and 213 m. n.w. of London. It stands in the hundred of Isled, near the middle of the vale of the Clwyd, on the sides and at the bottom of a rugged steep limestone hill, crowned by the imposing ruins of a castle built in 1284, by Henry Lacy, earl of Lincoln, where there had stood fortifications erected by William the conqueror, and where there are traces of still earlier castellated remains. The newer part of D. was built at the bottom of the hill, after the destruction and desertion of a great part of the town on the top of the hill, about 1550. D. has manufactures of shoes and leather for the English markets and export trade; but it is

more a place of genteel retirement than commerce. Pop. in 1871, 6,323. It sends one member to parliament; Ruthin, Holt, and Wrexham being contributory boroughs. In 1645, Charles I. took refuge in the castle after the battle of Rowton Heath. The garrison surrendered to the parliamentary forces, after a siege of two months. It was shortly afterwards dismantled. The fortifications have an area of a sq. m. in extent. A lunatic asylum for the five counties of North Wales was erected near the town in 1848. A noble institution for the maintenance of 50 female inmates, of whom 25 are orphans, was built in the town, and opened in 1860, with funds in the hands of the Drapers' company of London, from money left to them in 1540, by one Thomas Howell, a Welshman. It has an endowment of about £1500 a year. The charter of Henry de Lacy is preserved among the corporate archives.

**DENBIGHSHIRE**, a co. of North Wales, on the Irish sea, and between the Dee and the Conway. It is 41 m. long, with an average breadth of 17; contains 603 sq. m., has 8 m. of coast, and is the sixth in size of the Welsh counties. The surface is partly rugged and mountainous, with some beautiful and fertile vales, as the vale of the Clwyd, 20 m. by 7. In the n., is a horse-shoe range of hills, 65 m. long, and convex to the coast. The highest hill is Cader Fromwen, 2,563 ft.; and many others rise above 1500 feet. The rocks are chiefly Silurian clay and graywacke slates, with some granite and trap, and bands of Devonian, carboniferous, and permian strata. There occur coal, iron, slates, flags, millstones, limestone, lead, and copper. The chief rivers are the Dee, Conway, Elwy, and Clwyd. The Rhaiadr waterfall is 200 ft. high in two parts. Llangollen vale is famed for romantic beauty and verdure, amid hills of savage grandeur. The climate is mild in the lower parts, but cold and bleak among the hills, where small hardy sheep and ponies are reared. About two thirds of D. are under cultivation; its corn, cheese, butter, and live-stock are greatly esteemed. It is also well timbered. Salmon are caught in the rivers. D. is divided into 6 hundreds, 3 poor-law unions, and 64 parishes, in the diocese of Bangor and St. Asaph. The chief towns are Denbigh, Wrexham, Ruthin, Holt, Llangollen, Llanrwst, Abergele, and Ruabon. Pop. '71, 105,102, showing an increase of 74 per cent since the first census in 1801. D. returns three members to parliament—two for the county and one for Denbigh. D. was anciently occupied by the Ordovices, a powerful tribe, not entirely subdued by the Romans till the time of Agricola. Of British or pre-Roman remains there still exist tumuli, two cistvans or stone cells, barrows, and forts. To the times of the Welsh and Saxon struggles are referable the Pillar of Eliseg, near Llangollen, and the dikes of Offa and Watt. Offa's, the king of Mercia's dike, to keep out the Welsh, was a ditch, with small forts on mounds at intervals, and ran from Herefordshire to the estuary of the Dee; Watt's dike ran on the e. side of Offa's dike and parallel to it. Wrexham church is one of the seven wonders of Wales. Chirk castle is a fine Norman stronghold, lately restored.

**DENDERAH** (Gr. *Tentyra*, Coptic *Tentore*, probably from *Tēn-Athor*, the abode of Athor), a ruined t. of Upper Egypt, situated near the left bank of the Nile, in lat. 26° 13' n., long. 32° 40' east. It is celebrated on account of its temple, dating from the period of Cleopatra and the earlier Roman emperors, and one of the finest and best preserved structures of the kind in Egypt. The principal temple measures 220 ft. in length by about 50 in breadth, and has a noble portico supported on 24 columns. The walls, columns, etc., are covered with figures and hieroglyphics. Prominent among the former is that of Athor or Aphrodite, to whom the temple was dedicated. On the ceiling of the portico are numerous mythological figures arranged in zodiacal fashion, and which were long regarded as a representation of the zodiac; but the absence of the crab has led some recent archaeological travelers to doubt whether the figures were intended to have any reference to astronomy. There are many other sacred buildings at D., including a temple of Isis. The whole, with the exception of one propylon, are surrounded by a sun-dried brick-wall, 1000 ft. long on one side, and in some parts 35 ft. high.

**DENDERMONDE** (Belg. *Termonde*), a t. of Belgium, in the province of East Flanders, situated at the confluence of the Dender and the Scheldt, 18 m. e. of Ghent. D., which is said to have originated in the 8th c., is fortified, and has a citadel dating from 1534, and possessing the means of laying the surrounding country under water in case of attack: Louis XIV. besieged it in vain in 1667, but Marlborough, aided by a long drought, succeeded in taking it in 1706. [In connection with Marlborough's siege, D. is mentioned frequently in Sterne's *Tristram Shandy*.] The principal buildings of D. are the town-house and several churches, the most noteworthy of which is the church of Notre Dame, a very old edifice, containing two admired pictures by Vandyk. The manufactures are woolens, lace, cotton-yarn, etc., and there is a large weekly market for the disposal of the agricultural produce of the neighborhood. Pop. '70 about 8,300.

**DENDRERPETON**, a small lizard-like batrachian, found by Lyell and Dawson in the interior of the hollow trunk of an upright *sigillaria* in Nova Scotia. The tree was about two ft. in diameter, and consisted of an external cylinder of coal, and an internal axis of mud and sand, cemented together with fragments of wool into a solid rocky mass. In this was discovered the shell of a *pupa*, the first air-breathing mollusk met with in the coal, and the bones of a small reptile probably 2½ ft. long. It was described and figured by Owen as *D. Acadicum*. He showed it to be nearly related to *arch-*

*eyosaurus*, from the plicated structure of the teeth, the sculpturing of the broad cranial plates, and the structure and proportion of certain limb-bones. It received its name, "tree-lizard," from its having been found in a tree; and this was supposed to show that it had arboreal habits: it is, however, probable that the remains had been washed in with the mud and sand which form the matrix in which they are preserved.

**DENDRITE**, the name given to a peculiar branching mineral crystallization on the surfaces of the fissures and joints, or in the substance of rocks, having the appearance of moss, and often mistaken for fossil plants. The hydrous oxide of manganese is the mineral that generally assumes this form, occurring frequently in great abundance in limestone, steatite, trachyte, and other substances.

**DENDROBIUM**, a genus of parasitical plants, almost entirely confined to tropical Asia. The flowers are grotesque in form, but very beautiful, some of which are purple, some a deep yellow, and some green; and all are very fragrant. When artificially raised they require a high temperature.

**DENDROLITES**, petrified stems of trees or shrubs, which occur in all parts of the world in the formations called secondary, especially in the coal formation. They may be regarded as the remains of a former creation. They are of very various magnitude. In some places, gigantic stems are found, and these are often observed to have branches, fruit, and even leaves—these, however, only as impressions—whilst in other places only fragments occur, which, however, belong to trees having nothing in common with those now growing in the same regions—as, for example, beautiful stems of palms at Chemnitz in Saxony, etc. Such woods are generally changed into agate, or into pitch-stone, when they occur in ancient strata altered by volcanic fire. Concerning the question of their origin, opinions are still divided. Many of them are so hard and beautifully colored, that they are cut and employed for all artistic purposes. When cut into very thin plates, they exhibit under the microscope the structure of the wood so perfectly, that it is not only possible for botanists to determine the natural order or family of plants to which it belongs, but even the genus and species. They mostly belong to the *filices*, *cycadææ*, and *conifera*. Brongniart was amongst the first investigators of this department of science. He has had many followers, amongst whom, in our own day, Unger and Göppert have especially distinguished themselves. See Göppert *Monographie der fossilen Coniferen* (Leyden, 1850).

**DENDROPHIS** (Gr. tree-snake), a genus of serpents of the family *colubridæ*, remarkable for their extremely slender form, their beautiful colors, and the liveliness of their movements. Their eyes are very large and prominent. They are widely distributed over the warm parts of the world; none are found in Europe. They live chiefly among the branches of trees, and insects are their principal food.

**DENGUE**, or **BREAK-BONE FEVER**, also called **DANDY** and **BUCKET FEVER**, is a disease known in the southern states of North America and in the West Indies, where it was first described as having appeared in the years 1827 and 1828. It was very violent in its access, but not often fatal, and consisted chiefly of a severe attack of inflammatory fever, with great heat and redness of the surface, and well-marked rheumatic pains of the limbs both in the joints and muscles. It usually terminated by a copious perspiration after a few days.

**DENHAM**, **DIXON**, 1786-1828; an English soldier and traveler. After the Napoleonic wars he traveled in Europe, and in 1821, joined the English government expedition to Africa under Clapperton. Denham himself explored the region around lake Tchad, in 1823. In a fight with the Arabs he was wounded and separated from his company, but found his way back after great suffering, reaching England in 1825. He published *Narrative of Travels and Discoveries in Northern and Central Africa in the years 1822, 1823, and 1824*.

**DENHAM**, **SIR JOHN**, an English poet of the reign of Charles I., was the son of the chief baron of exchequer in Ireland, and was b. at Dublin in 1615. In 1631, he entered Trinity college, Cambridge, where, after studying three years, he took his degree. Turning his attention to literature, he wrote a tragedy, entitled *Sophy*, which in 1641 was acted with great applause at Blackfriars. Two years after, he produced the poem *Cooper's Hill*, which has done more to perpetuate his name than any other of his works. In 1647, he was engaged in the performance of secret services for Charles I.; but these being discovered, he was obliged to escape to France in 1648, returning thence to England in 1652. After the restoration, he was appointed surveyor-general of his majesty's buildings, and created knight of the bath. Towards the close of his life, the latter part of which was darkened by an unfortunate marriage, he was visited by insanity; but recovering for a short time, he commemorated the death of Cowley in one of his happiest poetical performances. His own death occurred in 1668. His verse is characterized by considerable smoothness and ingenuity of rhythm, with here and there a passage of some force.

**DENI'NA**, **CARLO GIOVANNI MARIA**, an Italian author, was b. 28th Feb., 1731, at Revello, in Piedmont; studied at Turin, and in 1754, was appointed humanity professor at Pignerolo, but was deprived of his office on account of his having written a comedy in which there was much that excited the professional animosity of the ecclesiastical

order. D. went to Milan, but was soon after recalled to Piedmont, and appointed professor of rhetoric in the university of Turin. In 1777, he published anonymously at Florence his *Discorso sull' Impiego delle Persone*, in which he sought to show how monks might be transformed into useful members of society. This, of course, again cost him his chair, and he was even banished from the metropolis. In 1782, he went to Berlin, on the invitation of Frederick the great. Here he lived for many years, and wrote a considerable number of works. In 1804, he was introduced to Napoleon at Mentz, to whom he dedicated his *Clef des Langues* (Ber. 1804), and was in consequence appointed imperial librarian at Paris, where died 5th Dec., 1813.—D.'s principal productions are: *Discorso sopra le Vicende della Letteratura* (2 vols., Turin, 1761), *Delle Rivoluzioni d'Italia* (3 vols., Turin, 1769–70), an excellent work, which was copiously abused by the apologists of ecclesiastical privileges; and *Storia Politica e Letteraria della Grecia Libera* (4 vols., Turin, 1781–82). D.'s other works were, for the most part, written in Prussia. Among them may be mentioned—*Essai sur la Vie et le Regne de Frédéric II.* (Berlin, 1788), *La Prusse Littéraire sous le Regne de Frédéric II.* (3 vols., Berlin, 1790–91), *Tableau Historique Statistique et Moral des la Haute Italie et des Alpes qui l'entourent* (Turin, 1805), and *Storia dell'Italia Occidentale* (6 vols., Turin, 1809–10).

**DENIS, SAINT**, according to tradition, the apostle of France and first bishop of Paris, suffered martyrdom in the 3d century. He was sent (as is said) from Rome about 250 A.D. to preach the gospel to the Gauls. After various detentions at Arles and other places, he arrived in Paris, where he made numerous proselytes. Pescennius or Sicinius Lescennius, who was then the Roman governor of this part of Gaul, ordered D. to be brought before him, along with other two Christians, Rusticus, a priest, and Eleutherus, a deacon. As they continued firm in their faith, in spite of threats, Pescennius caused them to be cruelly tortured, and afterwards beheaded, 272 A.D., or, as others say, 290 A.D. Gregory of Tours, Fortunatus, and the Latin martyrologists, state that the bodies of the three martyrs were thrown into the Seine, but taken up by a pious woman named Catulla, and interred near where they lost their lives. At a later period, a chapel was built over their tomb. In 636, king Dagobert founded on the spot an abbey, called St. Denis, which soon grew to be one of the richest and most important in the whole kingdom, and was long the sepulcher of the French kings. What measure of truth there may be in the above biography, it is impossible to say. The Acts of St. D., written about the end of the 7th or beginning of the 8th c., is founded merely upon vulgar traditions, and is full of absurdities. The Greek church makes St. Denis to be the same person as Dionysius, the Areopagite, first bishop of Athens. The Roman Catholic church celebrates his memory on the 9th of October. For a long time his name was the war-cry of the French soldiers, who charged or rallied to the words *Montjoie St. Denis*.

**DENIS, ST.**, a t. of France in the department of Seine, 6 m. n. of Paris. It is traversed by two small streams, the Croud and Rouillon, and is well built, with clean spacious streets. It is situated within the line of forts forming the outworks of the fortifications of Paris, and was itself formerly fortified, but its ramparts have been converted into promenades. St. D. has manufactures of printed calicoes and other cotton goods; also several flour-mills, dye-works, bleacheries, and chemical works. Its yearly market, at which there is an annual sale of about 180,000 sheep, is one of the oldest in France, and lasts for a fortnight. Pop. 76,29,500. The town is supposed by some to date from the foundation of a chapel raised above the tomb of St. Denis (q.v.). This chapel was replaced, some time after his death, by a church and abbey, built by Dagobert I., who was buried in the abbey church, which thereafter became the mausoleum of the kings of France. By a decree of the national convention in 1793, the abbey was ordered to be destroyed, and in 3 days 51 tombs were sacrilegiously rifled and demolished, and the bodies cast indiscriminately into ditches prepared for them. The building, stripped of its lead to furnish bullets for the revolutionists, remained roofless, and was used as a cattle-market, until the time of the empire, when Napoleon commenced its restoration, a work which was completed by succeeding governments, in a style surpassing even its former splendor. The crypt of the abbey church contains statues of the French kings and princes from Clovis to Louis XVI.

**DENISON, JOHN EVELYN**, for many years speaker of the house of commons and privy councillor, was b. in 1800; eldest son of John Denison, Esq., of Ossington, Nottinghamshire. Educated at Christ Church, Oxford; married, 1827, Lady Charlotte, third daughter of the fourth duke of Portland; represented Newcastle-under-Lyne from July, 1823 to 1826, and Hastings from 1826 to 1830; was a lord of the admiralty from 1827 to 1828; sat for Notts from 1831—when he was also returned for Liverpool—till Dec., 1832. On the division of the county under the reform bill, he was returned for South Notts until 1837. He was then without a seat until 1841, when he was returned for Malton, but exchanged this borough for North Notts in 1857. In May, 1857, on the elevation of Mr. Shaw Lefevre to the peerage, D. was elected speaker of the house of commons without opposition, and unanimously re-elected in 1859, 1866, and 1868. In 1872, he retired from the speaker's chair, in which he was succeeded by Mr. Brand, and shortly after he was created viscount Ossington. He was a D.C.L. of Oxford. He died in 1873.

**DENIZLI**, a t. of Anatolia, Asiatic Turkey, situated on a low hill rising out of a spacious plain, in lat. 37° 48' n., long. 29° 3' east. D. is chiefly occupied with bazaars and market-places, the inhabitants for the most part residing in the environs. The manufacture of leather and a kind of morocco forms the staple industry of the place. The pop. may now amount to 8,000 or 10,000; it was formerly much more numerous, but by an earthquake in 1715, no less than 12,000 people perished.

**DENMAN, THOMAS**, Baron, 1779-1854; chief-justice of England; the son of a physician, educated at Cambridge. His success at the bar was rapid, and he speedily rose to rank next to Brougham and Scarlett. His greatest point in advocacy was as counsel for queen Caroline. In this trial he made the king his enemy, and thereby retarded his own promotion. In 1818, he was elected to parliament, and took a seat with the whig opposition. He remained in the commons until his elevation to the bench in 1832. In 1830, he was attorney-general under the Gray administration. Two years later he was made lord chief-justice of the king's bench, and in 1834, was raised to the peerage. He resigned the office of chief-justice in 1850, and retired to private life.

**DENMARK** (Dan. *Danmark*), capital, Copenhagen, the smallest of the three Scandinavian kingdoms, is situated between 54° and 57° 44' 50" n. lat., and 8° 5' and 12° 45' e. long., excepting the small island of Bornholm in the Baltic, about 90 m. e. of Seeland, which lies in 15° e. longitude. D. is bounded on the n. by the Skagerak, a gulf of the North sea; on the e. by the Cattegat, the Sound, and the Baltic; on the s. by the states of the German empire; and on the w. by the North sea, which the Danes call the "Western ocean."

The following table gives the main divisions of the kingdom of D. and its principal colonies:

	Area in Eng. sq. miles.	Pop. in 1870.
Denmark proper, comprising the islands of Seeland, Fünen, Laaland, Falster, etc., and the peninsula of Jutland.....	14,553	1,784,741
The Faröe islands.....	495	9,992
Iceland.....	38,860	69,763
Greenland.....	25,000	9,825
Danish W. I. islands—viz., Santa Cruz, St. John, and St. Thomas.....	105	37,821
	<b>79,013</b>	<b>1,912,142</b>

The population of D. proper was in 1878 estimated at 1,940,000, and that of Copenhagen (Dan. *Kjøbenhavn*), the capital, at 250,000. In 1870, there were 5 towns in D., besides the capital, in which the population exceeded 10,000.

	Population.
Odense, chief town of Fünen.....	16,970
Aarhus, in Jutland.....	15,025
Aalborg, ".....	11,721
Randers, ".....	11,854
Horsens, ".....	10,501

The continental portion of D., which since the treaty of Vienna, of Oct. 30, 1864, has been almost wholly limited to Jutland, is, in point of fact, the north-western extremity of the German continent. The entire coast-line of D., along the North sea, Skagerak, Cattegat, Sound, Baltic, and Little Belt, exceeds 800 m.; but many parts of this range are entirely unavailable for purposes of maritime intercourse, in consequence of the shallowness of the water, or of the numberless sand-banks, bars, and small islands which skirt the coasts. Seeland, or *Sjælland*, the largest of the islands, and the seat of the metropolis, Copenhagen, has an area of about 2,000 sq. miles. Its surface is in general very flat, and only a few feet above the level of the sea, and the highest of its few isolated elevations is not 500 ft. above the sea. The island is generally fertile and well-wooded, more especially in the s., but in the n. the soil is in many parts arid. Fünen (Dan. *Fyn*), the island next in extent, with an area of about 900 sq.m., is divided from Seeland by the Great Belt, and from Jutland by the Little Belt. It is less wooded than Seeland, and is intersected by a range of hills of inconsiderable height. The smaller islands of Laaland, Langeland, Falster, and Moen, with an area of 2,000 sq.m., are grouped to the s. of Fünen and Seeland, and exhibit the same physical and geological characters. They evidently, at some earlier epoch of the world's history, formed, together with those two larger islands, one connected whole, with Jutland on the w. and Sweden on the east. The n.e. shores of Seeland are separated from the latter country by a channel 70 m. in length, and only 1½ m. in breadth at its narrowest point, known as the Sound, or the *Øre Sund*. Ear sound, so denominated from its resemblance to the human ear. This channel varies from 10 to 19 fathoms in depth. The western coasts of Seeland are divided from Fünen by the Great Belt, a channel 9 m. wide at its narrowest point, and from 5 to 25 fathoms in depth—while the western shores of Fünen are separated from the peninsula of Slesvig and Jutland by the Little Belt, which is about four-fifths of a mile wide. The peninsula of Jutland, whose area is about 9,600 sq. m., was anciently, and even comparatively recently, covered with forests; but since their

wasteful destruction, extensive tracts have become converted into sandy heaths, and in some parts it has been found necessary to sow bent-grass and plant trees, in order to prevent the mischief accruing to the cultivated lands by the clouds of dust raised by the wind. One third of Jutland has been rendered unfruitful by these causes, but where the few forests still remain, the neighboring districts are productive and well cultivated. Efforts have been made within the last few years to plant the heaths and drain the marshes of Jutland, and the results have on the whole been successful, more especially in regard to the latter, which are of considerable importance, since they supply large quantities of turf for fuel.

The coasts of D., both on the continent and in the islands, are indented with numerous bays or *fjords*, the largest of which is Limfjord, which intersects Jutland, and since 1825 has insulated its northern extremity by breaking through the narrow isthmus which had separated it from the North sea. It covers an area of 250 sq. miles. D. abounds in small lakes, the most considerable of which are Arre, Esrom, Fure, and Bavelse, all in the n. and w. parts of Seeland. But as no inland point is more than 30 or 40 m. from the sea, and the ranges of hills are low and interrupted, the country has no rivers properly so called. Intercommunication is, moreover, facilitated in the islands and in Jutland by various canals.

*Roads, Railways, etc.*—The high-roads and lesser country roads, together measuring upwards of 1000 m. in length, are in general in excellent condition. At the present time there are about 850 m. of railroad in the islands and Jutland. In 1875, the telegraphic lines extended to a length of 1734 m.; while the number of telegrams transmitted was 886,917.

*Climate, Soil, Productions, etc.*—The climate of D. is modified by vicinity to the sea, and is considerably milder, and the air more humid, than in the more southern and continental Germany. The cold is seldom very intense before Christmas, or after the middle of March. The summers are occasionally very hot; the weather generally may be characterized as very variable; rain and fogs are frequent. The main temperature in Copenhagen, whose climate may be regarded as representing an average of that of all D., is, in winter, 32.9°; spring, 43.5°; summer, 63.5°; autumn, 49.3° Fahrenheit. The alternations from winter to summer are rapid, and scarcely broken by the intervention of spring or the succession of autumn. Westerly winds prevail in the proportion of 48 per cent to all others. The total absence of mountains and large rivers, and the alluvial character of the soil, by precluding all mining operations, of necessity lead the peasantry to follow agriculture, in the pursuit of which more than half the population are engaged. The drought of the spring and the short and sudden heat of the summer are often detrimental to the grass; but there is seldom an absolute failure in the supplies, and the cereal crops are generally good. During the last half century, the cultivation of wheat has increased nearly 200 per cent, while that of rye and barley has decreased rather than augmented.

Rye is more extensively used for bread than any other of the cereals, the average returns for the last ten years showing that about 3 millions of tons were raised in the kingdom annually, valued at nearly 19 millions of rix-dollars; while, in spite of the relatively increased cultivation of wheat, the quantity and value of the latter scarcely reached the half of the above figures. Barley and oats, for which the Danish climate seems to be specially well adapted, yield the largest annual average returns—viz., for the former, 6½ millions of tons, valued at 29 millions of rix-dollars, and for the latter 7½ millions of tons at 21 millions of rix-dollars. Since the potato crops were attacked by disease in 1847, the cultivation of this tuber has declined, but the average yield may be reckoned at about 400,000 tons. According to the census of 1870, there were in D. 316,570 horses, 1,238,898 horned cattle, 1,842,481 sheep, and 442,421 swine. Of these there were exported in the same year 12,500 horses, 50,200 horned cattle, 21,000 sheep, three fourths of which belonged to Jutland, while the 60,600 swine exported had been nearly all raised in the islands.

The Danish fisheries are not so important a branch of industry as might be expected, when we consider the extended coast-line of the country. But it was recently calculated that the Danish fisheries had an annual value of £150,000, and employed 6,500 men. The principal fish in D. are porpoises, herrings, whittings, cod, flounders, mackerel, salmon, and eels. Oyster beds, which are included under the royalties of the Danish crown, are met with at Frederikshavn, Skagen, and in the Limfjord. No part of the Danish territories is rich in minerals; some coal is found in the island of Bornholm, gypsum at Segeberg, and salt at Oldesloe. Amber is collected on the western shores of Jutland. Peat is got wherever there are swamps; and from the absence of productive coal-mines, and the increasing scarcity of wood, it is of great value for fuel, and every village in the vicinity of such land has a certain portion assigned for its supply. Beech and birch are the prevalent trees, but oak, pine, and larch are also indigenous, and grow to perfection. Agriculture has been steadily improving in D. of late years, but the land is too much subdivided to admit of the expenditure of great capital; and, moreover, is seldom cultivated by the owners. The condition of the laboring classes is happy; they are more roomily and warmly lodged, and better clad, than in Great Britain, and their dwellings are always clean. The peasants still continue to manufacture much of what they require within their own homes, the women weaving linen and woolen stuffs for the

use of the household, and the men making their own furniture and simplest farm implements, and the wooden shoes which are worn by men, women, and children. Almost two thirds of the entire area of the country is arable land. The Danes have not hitherto availed themselves of the great natural advantages which the country possesses for manufactures and trade; and notwithstanding the rich porcelain clays in Bornholm, which afford valuable materials for the manufacture of earthenware, and the abundant water-power in every part of the kingdom, the industrial operations are very inconsiderable. There are, however, a few good porcelain and glass works, and iron-foundries, chiefly in Seeland and near Copenhagen; and of late years the manufacture of cards and ornamental paper has been brought to great excellence in Copenhagen, and at Silkeborg, in Jutland. Linen is the principal article of domestic manufacture in Seeland, but the supply does not suffice for the home-demand. Many of the restrictions which formerly cramped foreign commerce have of late years been removed, but the commercial legislation is still too protective to give free scope to individual enterprise.

*Exports and Imports.*—The principal articles of export are grain, butter, cheese, smoked and salted meats, brandy, liqueurs, horned cattle, horses, skins, hides, tallow, bristles, etc. Among the imports are sugar and molasses, wines and spirits, salt, drugs, spices, textile fabrics, timber, coal, coffee, tea, tobacco, rice, flax, hemp, etc.

The Danish official returns of the commerce of the country afford no clew to the money-value of the imports and exports, as they merely give the weight or bulk of the articles as rated by the customs. About two thirds of the export trade is carried on in native vessels. In 1875, the imports amounted to 1,220,425 tons, valued at £12,650,000; and the exports, 501,565 tons, at £9,483,000. In 1876, the Danish mercantile fleet consisted of 3,200 vessels, including 169 steam-ships, having 11,509 horse-power; total tonnage, 250,643.

*Revenue, etc.*—The estimated revenue for the financial year 1878-79 was 47,761,350 kroner, or more than 2½ million pounds sterling, and the expenditure was 71,457,681 kroner. Since the war of 1866, the Danish government has maintained a large reserve fund for the purpose of having means to provide against war or other emergency. The amount reserved in 1876 was 34,339,143 kroner. The interest of the fund thus accumulated constitutes a very considerable item in the annual revenues of the state; and the national debt, which, since 1866, has been undergoing a gradual reduction, and which in 1872 amounted to 123,032,612 kroner, was, in 1876, only 100,805,939 kroner. Till lately, the current coinage consisted of gold Fredericks d'or (16s. 4d.), silver specie-dollars (4s. 3d.), a rix-dollar (2s. 2d.), divided into 6 marks of 16 skil lings each. But under a law which came into force 1st Jan., 1875, a decimal system of currency has been introduced into D., the unit being the *krona*, divided into 100 øre. The krone is worth about 1s. 1½d., and is therefore about half the rigsdaler, which it has supplanted as unit. Since 1839, the Danish pound-weight has been made equal to half the French kilogramme, and its fractions reduced to corresponding equivalents. With a similar view of facilitating international commercial relations, the old Danish ship-measure of a læst (=150 cubic feet) was done away with in 1867, and the English tonnage system officially adopted. The present unit is the ship last, equal to 2 tons.

*Army, Navy, etc.*—According to law, all able-bodied adult Danes are liable to serve for eight years in the regular army, and for a similar period in the army of reserve. Exemption from this duty can, however, be obtained under definite conditions, and by payment of the appointed penalties. The kingdom is divided into five territorial brigades, subdivided into four battalions, each brigade furnishing its contingent of infantry and one regiment of cavalry. Exclusive of the reserve, the army on the peace-footing numbers 37,850 men and officers; and on the war-footing, 49,253. The budget for 1876 was charged 4,295,440 rix-dollars for the ministry of war. The Danish navy is recruited from certain maritime districts exempt from the liability of supplying men for the army. The old Danish fleet, of which D. was deprived by England in 1807, is now represented by a small but well-appointed force of 33 steamers (of which 6 are iron-clads), with a horse-power of 23,190. The navy numbered, in 1875, about 900 men and officers. The budget of 1876 was charged with the sum of 2,201,814 rix-dollars, for the year's expense of the ministry of marine.

*Education.*—The educational institutions of D. have reached a very high degree of perfection, and few countries, if any, can compete with her in regard to the excellence of the system, and its extensive application relatively to the amount of the population. Education is compulsory for children between the ages of 7 and 14 years, and poor parents pay only a nominal sum towards the government of parochial schools, of which there are about 3,000 in Denmark. There are six training-colleges for the teachers of these public schools. Classical and other higher-class education is afforded by a large number of colleges in the capital and more important provincial towns, with the university of Copenhagen for its center, whose professional and tutorial staff of about 50 university teachers is remarkable for the high order of instruction imparted. There are three public libraries in Copenhagen, of which the royal library, with 500,000 volumes, is especially rich in oriental and Icelandic MSS.

*Religion.*—The established religion of D. is Lutheran, to which the king must belong; but complete toleration is enjoyed in every part of the kingdom. The reformation was introduced in 1536, when Christian III. caused all the Romish bishops to be seized in

one day, formally proclaimed their deposition from their sees, and incorporated the property of the church with that of the crown. D. is divided into 7 dioceses, or *stifter* (besides those in the West Indian colonies)—viz., Seeland, Laaland, Fünen, Ribe, Aarhus, Viborg, Aalborg, besides Skalholt in Iceland; 1907 parishes, with numerous affiliated churches, 62 rectors, and 1677 parish ministers. The nomination of the bishops is vested in the king; they have no political character; but in other respects exercise nearly the same privileges within their dioceses as their English brethren of the same rank.

*Law.*—The supreme court of justice, presided over by four assistant judges, chosen by the landsting, in addition to the four ordinary high judges, holds its sittings at Copenhagen, and there are lower courts in the town. All civil cases are first carried before a court of conciliation, composed of persons from the vicinity, selected on account of their position and character. Their decisions are registered, and have legal force where both parties have engaged to abide by the judgment; otherwise, the case is carried to the higher courts. Appeals are allowed from all the lower courts to the supreme court.

*Constitution and Government.*—The succession to the crown was not necessarily hereditary till 1660, when the people and the clergy, impelled by hatred towards the nobles, in whose hands the supreme power of the state rested *de facto*, constituted themselves into a national assembly, which invested the sovereign (Frederick III.) for himself and his heirs with absolute power, and declared the succession to the throne hereditary. From that time, the crown exercised the *dominium absolutum*, unchecked by any constitutional restraint, till 1831, when Frederick VI., yielding to the pressure of the times, granted a constitution to his people, and established an assembly of notables for the islands and Jutland; the duchies being governed by their own constitutional forms. The nation was at first perfectly satisfied with the amount of power conceded by the king, but after a time the anomalous character of the authority vested in the assembly created great political agitation and discontent. This feeling continued to increase under the reign of Frederick's successor, Christian VIII.; and on the death of the latter, his son and successor, Frederick VII., saw himself obliged to depart from the conservative policy of his father, and to grant, in 1849, the constitutional form of government which D. now enjoys, and which is based upon the most liberal principles. The national assembly or rigsdag consists of the folkething and landsting, and is invested with very extensive powers: it meets annually for two months, and its members receive a fixed allowance during their sittings. The landsting is composed of 66 members, of whom 12 are chosen for life by the king, while the remainder are elected for a term of eight years by certain municipal and rural electoral bodies, who represent the large tax-payers of the kingdom. A fixed age, good reputation, and a certain moderate independent income are the only qualifications required for election to this branch of the rigsdag. The members of the Folkething, whose number (which is now 102) varies with the population, are elected for three years by universal suffrage, and, except that no fixed income is required in their case, they must have the same qualifications as candidates for the upper chamber. The rigsdag must meet every year, and must, in the course of their session, consider and dispose of the annual accounts that the finance minister is bound to submit to their scrutiny.

The king's person is inviolable; the ministry is responsible, and with the king as president, constitutes the executive royal privy council. The seven members of this body, who preside over seven distinct ministerial departments, are individually and collectively responsible to the rigsdag for their acts, and cannot under any circumstances be condemned or pardoned by the sovereign without the concurrence of that body. D. is divided for administrative purposes into 20 *amter*, or jurisdictions—viz., 10 for the islands, and 10 for Jutland, each presided over by a chief, or "amtmand," who in Copenhagen alone bears the title of "over-president." Primogeniture is still in force, but all other limitations to succession, and all remains of the ancient forms of land-tenure by socage or fixed terms of labor, are being entirely abrogated. The titles of nobility in D. are limited to counts ("grever") and barons.

*History.*—The Kymri were the earliest known inhabitants of Scandinavia, and made themselves formidable to the Romans 100 years B.C. To them succeeded the Goths, who, under their mythical leader, Odin, established their rule over the Scandinavian lands. Odin's son, Skjold, is reputed to have been the first ruler of D.; but the little that is known of Danish history in those remote ages, seems to indicate that the country was split up into many small territories, whose inhabitants lived by piracy. The people were divided into "Bonder," freemen, and "Trælle," bondsmen. The former busied themselves with war, and "Vikingetog," or piracy, and the government of the land; while to the latter were left the peaceful pursuits of hunting, fishing, and tilling the soil. The mission of Ansgarius, the apostle of the north, to Southern Jutland in 826, where he baptized Harald Klak, one of the Smaa Kongar, or little kings of D., was the means of first opening the Danish territories to the knowledge of the more civilized nations. The country was soon torn by civil dissensions between the adherents of the ancient and modern faith. Gorm the Old, the first authentic king of D., the bitter enemy of Christianity, died in 935, after having subjugated the several territories to his sway; and although his death gave fresh vigor to the diffusion of the new faith, paganism kept

its ground for 200 years longer, and numbered among its adherents many of those half-mythical heroes whose deeds are celebrated in the Eddas and the Kæmpeviser of the middle ages. The success that attended the piratical incursions of the Northmen, drew them from their own homes; and while Gorm's descendants, Svend and Knud, were reigning in England, D. was left a prey to anarchy. On the extinction of Knud's dynasty in 1042, his sister's son, Svend Estridsen, ascended the throne. Internal dissensions and external wars weakened the country, and the introduction of a feudal system raised up a powerful nobility, and ground down the once free people to a condition of oppressed serfage. Valdemar I., by the help of his great minister, Axel Hvide, known in history as bishop Absalon, subjugated the Wends of Rügen and Pomerania, and forced them, in 1168, to renounce the faith of their god, Svantevit, and accept Christianity. During the time of Knud VI., and in the early part of the reign of Valdemar II.—sons of Valdemar I.—the conquests of D. extended so far into German and Wendic lands, that the Baltic was little more than an inland Danish sea. The jealousy of the German princes and the treachery of his vassals combined to rob Valdemar II. of these brilliant family conquests. His death in 1241 was followed by a century of anarchy, and inglorious decadence of the authority of the crown, during which the kingdom was brought to the brink of annihilation under the vicious rule of his sons and grandsons. Under his great-grandson, Valdemar III., the last of the Estridsen line, D. made a quick but transient recovery of the conquests of the older Valdemars, and the national laws were collected into a well-digested comprehensive code. From his death in 1375 till 1412, his daughter, the great Margaret, first as regent for her only and early lost son, Olaf, and later as sole monarch, ruled, not only D., but in course of time also Sweden and Norway, with such consummate tact, and with so light yet firm a hand, that for once in the course of their history, the three rival Scandinavian kingdoms were content to act in harmony. Margaret's successor, Erik, the son of her niece, for whose sake she had striven to give permanence, by the act known as the union of Calmar, to the amalgamation of the three sovereignties into one, undid her glorious work with fatal rapidity, and, after an inglorious war of 25 years with his vassals, the counts-dukes of Slesvig-Holstein, he lost the allegiance and the crowns of his triple kingdom, and ended his disastrous existence in misery and obscurity. After the short reign of his nephew, Christopher of Bavaria, the Danes, on the death of the latter in 1448, again exerted their long-used ancient right of election to the throne, and chose for their king Christian of Oldenburg, a descendant of the old royal family through his maternal ancestress, Rikissa, the great-granddaughter of Valdemar II. Christian I., the father of the Oldenburg line, which continued unbroken till the death of the last king of D., Frederick VII., in 1863, laid the foundation of the Slesvig-Holstein troubles, which, after maturing for centuries, have ended in our own day in dismembering the Danish monarchy. Christian bought the empty title of count-duke of Slesvig and Holstein in 1460, by promising for his successors that they should forever leave the two provinces united, a pledge he had no right to impose, and they no power to keep; and by his failure to pay his daughter's dowry to her husband, James III. of Scotland, he lost for Norway her ancient provinces of the Shetlands and Orkneys, which had been given in pawn to the Scottish king. His unprofitable reign was followed by half a century of international struggles in Scandinavia. The insane tyranny of the otherwise able and enlightened Christian II., by exasperating the Danish nobles, and lashing the national anger of the Swedes to fury, cost him his throne, and gave him a lifelong cruel imprisonment among his subjects in D., who chose his uncle Frederick I. to be their king, while Sweden was forever separated from D., and raised under the Vasas (see GUSTAVUS I.) to be a powerful state. Christian III., in whose reign the reformation was established, united the Slesvig-Holstein duchies in perpetuity to the crown in 1533. His partition of the greater part of these provinces among his brothers became a source of much mischief to D., which did not end till 1773, when the alienated territory was recovered by the cession of Oldenburg and Delmenhorst to the grand-duke of Russia, the representative of the Holstein-Gottorp family. Frederick II., who increased the embarrassments connected with the crown-appanages, by making additional partitions in favor of his brother (the founder of the Holstein-Sonderburg family), was succeeded by Christian IV., 1588, who was the ablest of all the Danish rulers. His liberal and wise policy was, however, cramped in every direction by the arrogant nobles, to whose treasonable supineness D. owes the reverses by which she lost all the possessions she had hitherto retained in Sweden. The national disgraces and abasement which followed, led, in 1660, under Christian's son, Frederick III., to the rising of the people against the nobles, and their surrender into the hands of the king of the supreme power. For the next hundred years, the peasantry were kept in serfage, and the middle classes depressed; while the power of the crown rested in the hands of a Germanized nobility, who despised the language and usages of their country, and exerted the most baneful influence on the true national life. Many improvements were, however, effected in the mode of administering the laws, and the Danish kings, although autocrats, exercised a mild rule. The abolition of serfage was begun by Christian VII. in 1767, but not finally completed till twenty years later; it was extended to the duchies in 1804. The miseries of the reign of Christian's son, Frederick VI., due to the relations maintained by D. with Napoleon, brought the country to the verge of ruin. At war with Sweden, England, Russia, and Prussia, and with the finances in a depressed

condition, the kingdom was threatened with bankruptcy; and although it had speedily rallied from the injuries and losses inflicted by the battle of Copenhagen, under Nelson, in 1801, the fresh rupture with the allies, which ended in the compulsory surrender to the English of the entire fleet, after the destructive bombardment of Copenhagen, Sept. 1807, completely paralyzed the nation. By the congress of Vienna, D. was compelled to cede Norway to Sweden. The discontent that had long been brooding in the duchies, degenerated after the stirring year of 1830 into mutual animosity between the Danish and German population, which was not allayed by the schemes devised by the court to meet the difficulties of the case. The anticipated failure of heirs to the throne complicated the questions at issue; and the Holstein party, being encouraged by the diet at Frankfort, and perhaps still more by Prussia, came to an open rupture with D. in 1848, hastened, no doubt, by the reaction produced all over the continent by the French revolution, and thus, on the accession of Frederick VII., half his subjects were in open rebellion against him. After alternate hostilities and armistices, the Slesvig-Holstein war was virtually concluded in 1849, by the victory of the Danes over Slesvig-Holsteiners at Idsted, followed by the conclusion of peace between D. and Prussia. The liberal constitution granted by the king fully satisfied his subjects in D. proper, but disaffection still smoldered in the duchies.

On the death, in 1863, of Frederick VII., the present king, prince Christian of Slesvig-Holstein-Glücksborg, ascended the throne under the title of Christian IX., in conformity with the act known as the treaty of London of 1852, by which the succession to the Danish crown had been settled on him, and his descendants by his wife, princess Louise of Hesse-Cassel, niece of king Christian VIII. of D. With Frederick VII., the direct Oldenburg line had expired, and, at his death, the question of the succession to the duchies acquired an importance which it had never before possessed. A pretender, backed by German influence and help, at once started up in the person of the eldest son of the duke of Augustenborg, whose defeat in 1848, and solemn renunciation of all claims on the titles or possessions of the Danish royal house, in consideration of his receiving a free pardon, and accepting a large sum of money from the crown, had been regarded in D. as the final settlement of his pretensions.

The cause of the Augustenborg prince, who assumed the title of duke Frederick VII. of Slesvig-Holstein, was speedily merged and lost sight of by Prussia and Austria in their direct aim of incorporating the duchies with the German confederation. D., unaided by the neighbors and allies on whose support she had relied, was forced to go single-handed into the unequal contest. After a brave but utterly futile attempt at resistance, the Danes found themselves forced to submit to the terms conceded to them by their powerful foes, and resign not only Lauenborg and Holstein, but the ancient crown-appanage of Slesvig into the hands of the German confederate powers. By the peace of Vienna, 1864, the Danish king bound himself to abide by the decision which Prussia and Austria should adopt in regard to the destiny of the severed Danish provinces. The dissensions between these two great powers, which led to the Austro-Prussian war of 1866, and resulted in the triumph of Prussia, have left the fate of the Slesvigers entirely in the hands of the latter state, which has hitherto refused to relinquish its hold upon the province. Since the war, D., although reduced to the narrow limits of the islands and Jutland, has recovered from its fall, and the degree of political and social freedom enjoyed by the nation now perhaps as high as is to be found in any country in Europe.

**DENNER**, BALTHASAR, 1685-1747; a German portrait-painter employed by Frederick the great; went to England by invitation of George I., where he was not appreciated. His chief peculiarity consisted in the fineness of his mechanical finish, which extended to depicting even the almost invisible furze or hair growing on the smooth skin. Charles VI. paid 4,700 florins for a "Head of an Old Woman" by this artist.

**DENNERY**, or **D'ENNERY**, ADOLPHE PHILIPPE, a French dramatic writer of Jewish extraction, was b. at Paris on June 17, 1811. His first employment was that of clerk to a notary; he gave that up to become a painter; and afterwards, while still very young, he became a contributor to the newspapers. The first dramatic work in which he had a hand was brought out in 1831; this was *Emile, ou le Fils d'un Pair de France*, and it was produced by him in concert with M. Charles Desnoyer, a well-known *littérateur* and theatrical critic. It had some success, and D. followed it up with two or three others, which had so much popularity that his services as a play-writer came into considerable demand. He was a ready writer, and always able to come up to a fair standard of merit; and, encouraged by the theatrical managers of France, he has been one of the most prolific of dramatic authors. He has produced, by himself or in concert with others, about 200 pieces in one style or another; and a few years ago, five of his pieces were to be seen upon the Parisian stage at one time. Latterly, D. has been a man of business as well as an author. He was appointed director of the Théâtre Historique in 1850, but resigned this appointment almost immediately. An attempt which he made in 1855 to establish a new theater, which he first proposed to call the Théâtre du Peuple, and afterwards the Théâtre du Prince Impérial, did not succeed; but since that, he has had a large share in establishing and in managing a public company, in which many persons connected with the press and with the theaters were concerned—

the Société Thermale de Cabourg-Dives. Of this company, whose speculation consisted in developing the attractions of a new watering-place (in the dep. of Calvados), he has been successively secretary and managing director. D. was decorated with the legion of honor on the 10th Dec., 1849, and was promoted to the rank of officer on the 16th of Aug., 1859.

**DENNEWITZ**, a small village in the province of Brandenburg, Prussia, 42 m. s.s.w. of Berlin. Here was fought, on the 6th of Sept., 1813, a battle between 70,000 French, Saxons, and Poles, commanded by marshal Ney, and 45,000 Prussians, under gen. Taubentzien. The fighting was obstinate to the last degree. Both armies more than once drove each other from their positions, but the patriotic enthusiasm of the Prussians finally prevailed, and Ney gave the order to retreat. At this moment Bernadotte, crown-prince of Sweden, appeared at the head of 70 battalions of Russians and Swedes, supported by 10,000 horse, and preceded by 150 pieces of cannon. These fresh troops turned the retreat into a complete rout, until the whole of the French army presented nothing but a vast mass of fugitives. The French lost 15,000 killed, wounded, and prisoners (the Germans say 20,000), and 43 pieces of cannon. The allies lost 6,000 killed and wounded, of whom 5,000 were Prussians. The most important feature of this victory to the Prussians was that most of their troops were *landwehr* (militia), for whom Napoleon had expressed the utmost contempt, designating them a "rabble."

**DENNIE**, JOSEPH, 1768-1812; b. Mass.; graduated at Harvard in 1790. In 1795, he became connected with the *Tablet*, a Boston weekly journal; and the same year established *The Farmer's Weekly Museum* at Walpole, N. H., in which he published, over the signature of "The Lay Preacher," a series of papers which attracted universal attention. In 1801, he began the *Portfolio* at Philadelphia, and adopted the *nom de plume* of "Oliver Oldschool." This publication was the channel through which the letters of many great men appeared.

**DENNIS**, a t. in Barnstable co., Mass., 65 m. s.e. of Boston; pop. 70, 3,369. The township extends quite across the peninsula, and is intersected by the Cape Cod railroad. Most of the people are engaged in ship-building, navigation, and fishing.

**DENNIS**, JOHN, the son of a London saddler, was b. in London in 1657. He was put to school at Harrow; and afterwards, in 1675, he went to Caius college, Cambridge. Four years afterwards, he removed to Trinity hall in the same university, and in 1683, took there his degree of M.A. After leaving Cambridge, he traveled on the continent, passing through France and Italy. Returning home, and in the possession of a small fortune, he joined the whigs, and brought a sufficiently rancorous pen to the assistance of his party. He formed the acquaintance of Dryden and Wycherley, and other distinguished wits of the time, and instigated by companionship, as well as by native bent, he made various attempts as a theatrical writer. D. was expensive in his habits; and having dissipated his fortune, he had to depend for subsistence during the remainder of his life on private patronage and his pen. For several years, he enjoyed a small annuity procured for him by lord Halifax, but that he outlived. He became blind before he died; and in his distress, some of those he had flattered, and some of those he had abused, got up a play for his benefit. He died in 1734. D. had an ungovernable temper, and made many enemies; and his name, which his own writings could not preserve, will live for ever in their contempt and hate. He is one of the best abused men in English literature. Swift lampooned him, Pope assailed him in the *Essay on Criticism*, and finally "damned him to everlasting fame" in the *Dunciad*.

**DENON**, DOMINIQUE VIVANT, Baron, was b. at Châlons-sur-Saône, Jan. 4, 1747. At an early period, he went to Paris, to study law, but quickly betook himself to the fine arts, and acquired a high reputation as an amateur and art critic. During a residence in Southern Italy, he spent much of his time in studying etching and mezzotint engraving, and along with the abbé St. Non, wrote a *Voyage Pittoresque de Naples et de Sicile* (Par. 1788). Afterwards, he lived at Venice, and other Italian cities, but returned to France during the revolution. Having, at the house of Mme. Beauharnais, formed the acquaintance of Bonaparte, he was chosen by him to accompany the expedition to Egypt in the capacity of a *savant*. He was indefatigable in drawing the relics of ancient Egyptian art. In 1802, he published his *Voyage dans la Basse et la Haute Egypte*, the engravings attached to which admirable work are very correct, and prove D. to have been a skillful artist. As a member of the Egyptian institute, he had also the most important part in the *Description de l'Egypte* drawn up by that learned body. Bonaparte now made him inspector-general of museums, in which capacity he exhibited great ability. He accompanied Bonaparte in various subsequent expeditions, and suggested to him what art-treasures of the conquered cities would be most suitable for the Louvre. After 1815, he was dismissed from his office. The remaining years of his life were occupied in preparing for publication a history of art, to be illustrated by the best artists, but he did not live to finish it, having died 27th April, 1825. D.'s work was completed by Amaury Duval, and published in 1829, under the title *Monuments des Arts du Dessin chez les Peuples tant Anciens que Modernes*. D. himself executed as many as 300 etchings, chiefly imitations of the style of Rembrandt.

**DÉNOUEMENT** (Fr. from *dénouer*, to untie, which again is from *nœud*, a knot). In fiction this term is generally applied to the termination or catastrophe of a play or romance; but, more strictly speaking, it designates the train of circumstances solving the plot, and hastening the catastrophe. A good dénouement in a novel or play should be natural, as a result of the preceding plot, and yet should not be so obvious as to be easily anticipated. Forced and arbitrary solutions of plot, offending against nature and common-sense, are frequently perpetrated for theatrical effect (*coups de théâtre*).

**DENS, PETER**, a well-known Roman Catholic theologian, was b. in 1690, at Boom, a small Belgian town, situated on the river Rupel, about 10 m. s. of Antwerp. Apparently, nothing is known—at least by Protestant writers—regarding the incidents of his life, as his name appears in no encyclopædia or biographical work that we are acquainted with. The scanty information we possess is derived from the epitaph inscribed on his tomb in the chapel of the archiepiscopal college of Malines by the present (1857) rector. From this epitaph it appears that he was reader in theology at Malines (something equivalent to our professor of divinity) for twelve years, *plebanus* or parish priest of St. Rumold's or Rumbold's church in the same city, and president of the college of Malines for 40 years. He also held various honorary church offices. He was canon and penitentiary, synodical examiner and scholastic archpriest of St. Rumold's—the metropolitan church of Belgium. He died 15th Feb., 1775, in the 85th year of his age. The work which has rendered D.'s name familiar, even to the Protestant public, is his *Theologia Moralis et Dogmatica*. It is a systematic exposition and defense—in the form of a catechism—of every point of ethics and doctrine maintained by Roman Catholics, and is extensively, if not generally, adopted as the text-book of theology in their colleges. It appears to owe its popularity more to its being a handy and usable compilation than to any great talent exhibited by its author. The casuistical parts of the work have been severely criticised by Protestant moralists. The edition we have consulted is the Dublin one of 1832.

**DENSITY**. When of two bodies of equal bulk or volume, the one contains more matter than the other, it is said to have greater density than that other. The quantity of matter is measured by the weight, and thus density and specific gravity come to be proportional to one another. Platina, which is about 21 times the weight of water, long passed for the densest body; but Breithaup of Freiburg, in 1833, made out *iridium* to be twice as dense. Rare is opposed to dense, and the rarest body known is *hydrogen*, which is about 14½ times rarer than atmospheric air. The density of bodies is diminished by heat, and increased by cold. See **HEAT, MATTER**.

**DENT**, a co. in s.e. Missouri, reached by a branch of the Atlantic and Pacific railroad; 750 sq. m.; pop. '70, 6,257—31 colored. The soil is fertile; productions agricultural. Co. seat, Salem.

**DEN'TA**, or **GYENTA**, a market t. of Hungary, situated on the Berzava, about 30 m. s. of Temesvar. It has several large annual fairs. Pop. '69, 2,919.

**DENTAL SYSTEM**. See **TEETH**.

**DENTALIUM** (Lat. *dens*, a tooth), a genus of marine gasteropodous mollusks, of the order *tubulibranchiata*, having two symmetrical *branchiæ* (gills), which are inclosed, along with all the other soft parts of the body, in an elongated shelly tube. The tube is conical, somewhat curved, and has a considerable resemblance to an elephant's tusk in miniature. Until recently, from a mistake originating in the similarity of its branchiæ to those of some of the *annelides*, the D. was ranked in that order. Fossil species abound in the tertiary formations.

**DENTARIA**, a genus of plants of the natural order *crucifera*, having a lanceolate compressed silique. One species only, *D. bulbifera*, is found in Britain, and is a rare plant, with a simple stem, the lower leaves pinnate, the upper leaves simple, and rose-colored flowers, the axils of the leaves producing bulbs, and the creeping rhizome having tooth-like knobs, whence the name D., and the English name coral-root. The root, when dried, is said to have greater pungency than pellitory of Spain, and was formerly used in the same way for toothache. *D. diphylla*, a North American species, is called pepper-root from the same property.

**DENTATUS, MANIUS** (or **MARCUS**) **CURIUS**, a Roman consul in the first half of the 3d c. B.C. He was made consul in 290, and conquered the Samnites; he defeated Pyrrhus in two important engagements in 275, and the next year reconquered the Samnites, and also defeated Lucanians and Bruttians. At the close of his third term as consul he retired from public life and cultivated his farm. He was elected censor in 272, and while in office built an aqueduct to bring water into the city, and a canal for draining marshy land. His name "Dentatus" was given because it was said that he was born with teeth.

**DENTEX**, a genus of acanthopterous fishes of the family of *spardæ* (Sea-breems, etc.). having a deep compressed body, and generally perch-like form; a single dorsal fin, the anterior rays of which are spinous; scaly cheeks; and many small conical teeth, among which are in each jaw at least four large canine teeth, elongated, and curved inwards. One species (*D. vulgaris*), the *Dentex* of the ancient Romans, abounds in the Mediterra-

nean, and has occasionally been taken on the southern shores of Britain. It is sometimes called the four-toothed sparus. It attains a large size, sometimes 3 ft. in length, and 20 to 30 pounds weight. It is an excessively voracious fish, as its large canine teeth might be held to indicate, devouring other fishes; but is itself in much request as an article of human food, and great numbers are taken in the mouths of rivers in Dalmatia and the Levant. It is there also a considerable article of commerce, being cut in pieces, and packed in barrels with vinegar and spices, in which state it will keep good for twelve months. It was preserved in the very same way by the ancients.

**DENTIFRICES** are substances, generally powders, which are employed as aids in cleaning the teeth. Charcoal and cuttle-fish bone-powder are useful as detergents; chalk, as a soft powder; and pumice, as a hard gritty substance for occasional use, when the teeth are more than ordinarily colored. Catechu, cinchona, and rhatany are employed to give astringency to the tooth-powder; myrrh, to impart odor; and bole armeniac, to communicate a red color. Common salt, cream of tartar, phosphate of soda, and sulphate of potash, are occasionally used; and where the breath has an unpleasant odor, the addition of 4 parts of bleaching-powder (chloride of lime) to the 100 of the tooth-powder, removes the fetid character of the breath, and also tends to whiten the teeth.

**DENTILS** (Lat. *dens*, a tooth), in the Ionic, Corinthian, and Composite orders of architecture, are ornaments resembling teeth. See **ENTABLATURE**.

**DENTINE** is the thin layer of cement or enamel which more or less coats the teeth of the mammalia, and from the compactness of its structure and fine texture, it is generally called the ivory of the tooth. It is very hard and durable, and consists mainly of phosphate of lime accompanied by gelatine.

**DENTIROSTRES**, a tribe or sub-order of birds, of the order *insessores*, characterized by a bill with a marginal notch towards the extremity of the upper mandible. It is composed chiefly of insectivorous birds, although the shrikes (*laniadæ*), which belong to it, prey also on small birds, quadrupeds, and reptiles. Among the other families of *D.* are *merulidæ* (thrushes, etc.), *sylviadæ* (warblers, etc.), *ampelidæ* (chatterers), and *muscipidæ* (flycatchers, etc.).

**DENTISTRY**, the art of the dentist, or that of treating disease in the teeth (*dental surgery*), and of replacing these organs when lost (*mechanical dentistry*).

1. *Dental Surgery*.—The disorders to which the teeth are liable are those arising from defective development, such as imperfections in form or structure, irregularity of position, etc.; these, again, constituting diseases more properly so called, such as caries or dental decay, necrosis or death of a tooth, inflammation or neuralgia of the soft tissues connected with them, such as the gum, the central pulp or *nerve*, etc.; lastly, those arising from accident of various kinds, such as blows, falls, and the like.

The treatment of all these different affections is generally of a *local* kind; or, in other words, confined to the spot in which the disease manifests itself. But dental diseases themselves are not always of a purely local nature; and it may be generally stated that wherever a tooth becomes diseased without any well-marked or ostensible cause, such a tooth has been originally defective or weak. It has been, in fact, imperfectly developed, and this imperfection is due to *constitutional* causes, or such as affect the general health of the individual. In this way, a very slight cause is sufficient to excite disease in, and lead to the destruction of, such a tooth. Disease impairs what of such little vitality it already possesses; it become less and less able to resist the action even influences as it is naturally exposed to in the mouth—chemical decomposition is set up, and the substance of the tooth is broken down, and decays—literally, rots away. This, in most cases, constitutes the pathology of dental caries; but there seems no doubt that in other instances caries, like any other morbid action in the bodily tissues, may commence in teeth previously quite healthy.

The object of the dentist, in these circumstances, is two-fold: he either attempts to arrest the decay, and repair its ravages; or he removes the diseased tooth altogether. These operations, along with supplying artificial teeth when the natural ones are lost, constitute, with those for the treatment of various minor affections, the main offices of dentistry.

Premising that all operations in dentistry require to be modified according to different cases, we shall shortly describe the various manipulations required in their performance.

*Scaling*.—This is a little operation, by which the accumulation of a substance termed "tartar" is removed from the teeth. Tartar is a deposit from the saliva, and lodges in greatest quantity most commonly behind the lower front teeth. Where it accumulates it is generally accompanied by absorption of the gums, whereby the necks of the teeth are exposed, and they become loosened, and fall out. Its removal is effected by little hoe-shaped steel instruments, bent in a manner to reach more easily those situations in which the tartar is found. Their mode of use is by inserting the point of any one of them under the free edge of the mass of tartar, at the gum, and lifting it away from the backs of the teeth to which it is adherent. The teeth are then freed from any par-

ticles still sticking about them, and their surface smoothed by being rubbed with pumice-powder or chalk.

*Regulating.*—The teeth of the second, or permanent or adult set, are very liable to be crowded and misplaced, one overlapping the other, or those of the upper jaw falling behind those of the lower when the mouth is closed, thus producing the prominent condition of the under-jaw denominated "under-hung." To remedy these defects, a variety of means have been adopted by dentists; the principle upon which all of them act, however, being that of pressing the displaced tooth or teeth into the natural position. This, of course, requires that room or space should exist for them to be thus adjusted; and where this is not the case, the usual procedure is to remove one or more of the back-teeth, or any others which it is less desirable to preserve. Some considerable time is necessary to complete the regulation of misplaced teeth; and even after they have assumed their proper position, they require to be carefully maintained there, otherwise a tendency to resume their former irregularity soon manifests itself.

*Stopping or Filling.*—This is one of the most important and delicate operations the dentist has to perform. The first step to be taken in filling or "stuffing" a tooth, as it is sometimes called, is to clear away all decayed and decaying substance. For this purpose, a number of slender digging and excavating steel instruments, termed "excavators," are required. With these the hollow in the tooth is scooped out and thoroughly cleaned. If pain be occasioned by this process, the operation of "destroying the nerve," as it is called, had better at once be resorted to. This is performed in several ways. Where the tooth is single-fanged, as in front-teeth, the nerve, or more correctly the pulp, may be bored out by passing a slender broach, or square and pointed steel wire, up into the central cavity of the tooth, with a slight rotary motion. When this cannot be done, however, the best plan is to destroy the nerve by some caustic application, such as arsenious acid, chloride of zinc, carbolic acid, etc., carefully applied. The method of doing this is to clean the tooth thoroughly out, and then to apply a little of the caustic on a pellet of cotton wool about the size of a barley-pickle or a grain of rice—pressing it well into the decayed hollow, and then filling it over with soft bees-wax. This should be allowed to remain there for six, eight, or twelve hours; it may at the end of that time be taken out, and the stopping proceeded with.

The cavity being properly shaped and cleaned out until its walls are of sound and hard tooth-bone, it is to be well dried, and the plug of stopping-material inserted. Various substances are employed for this purpose, and the mode of using each is somewhat different. For temporary stoppings, pure gutta-percha is a serviceable material. A quantity sufficient to fill the cavity, and somewhat more, is to be gently warmed over a spirit-lamp—not in hot water—and when quite plastic, is to be firmly pressed with a blunt-pointed stopping-instrument or "plugger," into all the interstices of the hollow in the tooth—more and more being pressed in, until the surface of the plug so formed is on a level with the surface of the tooth, when all the superfluous portion should be removed, and the solid plug smoothly finished.

A set of stoppings known as osteo-plastic fillings have recently been introduced, and are inserted into the tooth in a soft condition, where they harden in the course of a few minutes.

Another variety of stopping-material consists of amalgams of different kinds. Many absurd statements have been made regarding the evil effects of amalgam stoppings, but the only real disadvantage attending their use is shrinkage, and that many of them get black in the mouth, and discolor the tooth, while some that do not get black are friable, and crumble away in a short space of time. They are to be readily obtained, made up, and under various names. None of them seem very much superior to what is known as the platinum and gold alloy amalgam. The amalgam, then, whatever one it may be, is to be rubbed up with mercury to a firm, plastic consistence, and carefully introduced into the dried cavity in the same way as described regarding the gutta-percha, and is to be finished off in precisely a similar manner.

Gold-stopping is an operation of a much more complicated and difficult description. The materials used here are either gold-foil—that is, thick gold-leaf—or the peculiar substance, or rather the peculiar form in which gold exists, known as sponge-gold, or "pellets" of gold made up in a soft spongy condition of various sizes ready for use. In stopping a tooth with gold, even more care is necessary in preparing the cavity than what has been already inculcated. Its *shape* must now be particularly taken into account, and the nearer it approaches to a cylindrical form the better. The gold-foil, when it is employed, should be cut into strips, their breadth varying according to circumstances. Various modes of packing the gold are adopted, the chief object being that the foil shall lie in the cavity in such a way that its edges, and not its flat surfaces, shall be presented at the surface of the plug; otherwise the plug will be liable to injury by layers of it peeling off. In stopping with sponge, or other forms of gold, the preparatory steps are the same as for foil-stopping; it is, however, necessary to be more careful that no moisture be allowed to interfere with the operation.

The surface of a gold plug, formed in either of these ways, should be well consolidated by hard pressure with a blunt plugger, or lightly hammered with a suitable mallet, and the superfluous portion being removed, it ought to be burnished until it assume a brilliant metallic lustre.

*Extraction.*—This is the principal surgical operation falling to the dentist. It is most commonly demanded in consequence of what is termed toothache—a disorder which, however, is not always one and the same in its nature. This want of uniformity in the nature of those diseased states to which teeth are subject, and which are comprehensively denominated toothache, leads to the conflicting results obtained from those applications recommended for its cure. These remedies are numerous, and of various characters. To explain their mode of action, and the particular symptoms indicating the selection of each one in preference to another, would here be out of place. Their intention, in general, is either to destroy the nervous fibers existing in a tooth, or to narcotize and render them insensible. Among those acting in the former manner are such as creosote, arsenious acid, carbolic acid, pepsine, chloride of zinc, nitrate of silver, alum, tannin, etc.; among those acting in the latter mode are chloroform, laudanum, ether, spirit of camphor, etc. There is no necessity for describing the method of their application, further than to remark, that in all cases the decayed cavity should previously be well cleaned out, otherwise the remedy employed may be altogether prevented from reaching the spot where it is intended to act.

Where extraction comes to be demanded, it is performed by means of instruments adapted to the special peculiarities of the tooth requiring removal, or to the circumstances in which it exists. The great matter is, that each tooth should be extracted in accordance with its anatomical configuration; and to accomplish this, of course, requires an intimate knowledge of the natural form proper to each of these organs individually; without this, it is impossible to extract any tooth upon a correct principle. The tooth is grasped, as far as the instrument can be made to do so, by that portion of the root or fang which just emerges from, or perhaps which is just within, the socket; it is then loosened, not exactly by pulling, but rather by moving it in a lateral or in a rotatory manner, in strict accordance with the respective character of fang possessed; and finally, on its being thus detached from its connection with the jaw, it is, with very little force, easily lifted from its socket.

Anæsthetics are employed in the extraction of teeth in the same manner as for other surgical operations, where it is desirable to abolish pain. Ether and chloroform are the only agents of this nature which have as yet been found generally fit for practical application in any operation of a prolonged character. Chloroform tends to depress the circulation when far pushed, and in this way should be watched with care during its administration. Ether, again, has little of this tendency, but requires larger time to induce insensibility, is more exciting and persistent in its effect, while the odor of this preparation remains about the patient for hours. Both of these agents are liable to occasion sickness, and as a variety of accidental and collateral difficulties may arise during their exhibition, they ought not to be given by inexperienced hands.

An anæsthetic proposed at the end of the last century—namely, nitrous oxide or laughing-gas, has been revived, and its application in dental surgery has been of much service, answering all the purposes of chloroform or ether in short operations. Like these, it requires careful employment, and in some cases it would better be avoided if possible—such as in elderly patients of a full habit, or those who may have suffered from any lesion of the nerve centers, from hæmoptysis, etc. Other modes of inducing insensibility, local or general, have been proposed from time to time, but one after another has been abandoned as unserviceable. All over the world quack nostrums are found for rendering this operation painless; these, however, do not demand consideration here, as had any one of them afforded the least chance of success, it would long ago have been gladly welcomed and generally adopted by dentists.

2. *Mechanical Dentistry.*—The manufacture of artificial teeth, and other matters comprehended in mechanical dentistry, involve many subjects of which no adequate or satisfactory idea can be conveyed by mere description. Nothing beyond a mere outline of the materials employed and the leading processes involved in this branch of art, can be given without practical illustration. The various conditions of the mouth requiring the adaptation of artificial teeth, range from cases where only one tooth may be wanting, to those where not a single tooth remains in the jaw, above or below. Accordingly, artificial teeth are spoken of as partial or complete sets—a partial set being one for either upper or lower jaw, where some of the natural teeth still remain; a complete set being one for either jaw, where none are left, or for both jaws, when both are in such circumstances.

The simplest form of partial sets is what is termed a pivoted tooth. This is an artificial tooth fixed in the mouth upon the fang or root of one whose crown has been lost by decay or otherwise. The mode of procedure is as follows: An artificial tooth, as near as possible to the color and form of that to be replaced is selected. This artificial tooth may be either the crown of a natural human tooth corresponding to that lost, or one made in imitation of this, in a species of pottery-ware, and by a process much too long for detail in this place. Such *mineral teeth*, as these last are termed, are manufactured on an extensive scale, and sold ready for use to dentists. A tooth of either kind, then, being selected, is accurately fitted to the root remaining in the mouth, and, by means of a gold pin, adjusted to, and inserted into the open central canal existing in the root—the other extremity of this gold pin being attached

to the substitute tooth—the whole is fixed in its natural position, in a manner that renders detection almost impossible.

When more than one tooth is required, and occasionally even where only one is necessary, a somewhat different contrivance is had recourse to. What is called a "plate" requires to be fitted to the gum and remaining teeth in so precise and perfect a manner as to lie quite firmly and steadily in its place, and to which the artificial teeth required are subsequently fixed.

This "plate" is frequently made of gold, silver, or platinum plate, of the thickness of card-board, in which case, the name of "plate" is used in its literal signification. But such plates may be made of other substances besides those of gold, silver, etc., such as the ivory of the walrus, or the hippopotamus's tusk, formerly used, but now almost entirely superseded by vulcanized caoutchouc (q.v.) or vulcanite. The first step in any of these processes is to obtain an exact model of the gum and other parts upon which the plate is to rest. This is obtained by introducing bees-wax, or gutta-percha, or other modeling compound, softened by previous heating, into the patient's mouth, and pressing it forcibly upon those parts of which an impression is desired. On removing the wax or other substance from the mouth, Paris plaster is poured into the mold thus procured, and on its hardening, or "setting," this plaster-cast presents an exact counterpart of the gum. It is upon this plaster-model that all the subsequent operations are performed in fitting the artificial set. The following is a very brief sketch of the principal steps in working each of the most ordinary methods employed for these purposes:

*Metallic-plate Sets.*—Where the framework lying upon the gum is to be of gold or silver plate, or the like, it is necessary to procure, besides the plaster-model, a metal one. This metal-model is generally cast in zinc, gun-metal, or some such material; and a counter-model of a softer metal, generally lead, is taken from this again, so that a complete pair of dies is in this way procured. The gold or other plate, cut of a convenient size, is then stamped between the two metallic dies, and so made to assume the precise form desired. It is then trimmed, and any more delicate adjustments made upon it, such as soldering bands or clasps round those parts where it is to embrace any teeth remaining in the mouth, and finally completed by having the individual artificial teeth added to it, and adapted to the comfort and convenience of the wearer. The mode of fastening the teeth to the plate is in one of two ways. One kind of teeth have a tube extending along their whole length, and these are fastened by means of a pin fixed to the plate, upon which the tooth is secured by this pin passing up the tube alluded to. The other kind are provided with short platinum pins, fixed in the material of the tooth during its manufacture, to which pins a piece of gold or other plate is soldered, or a mass of gold fused upon them, and this, again, soldered to the framework of the set itself, wherever they are required.

*Vulcanite Sets.*—The first step in the manufacture of a vulcanite set of teeth is to make a pattern set in wax, with the mineral teeth constructed for the purpose, and which are to be used in the piece when it is finished, fixed in the wax; the whole constituting, in short, an exact fac-simile of what the completed set is intended to be. This pattern set is, of course, made upon and fitted to the plaster model, and is adjusted to the wearer's mouth precisely as if it were the set to be worn there. When everything is thus prepared, a duplicate of the wax-set is made in vulcanite—the vulcanite replacing the wax, and the mineral teeth being retained as they were. The process by which the vulcanite is made to take the place of the wax consists in imbedding the pattern set in Paris plaster, so that the mold of it, thus secured, may be separable into at least two parts. On these being taken asunder, the wax of the pattern set is melted out with boiling water, leaving the teeth *in situ*. The wax is then replaced by raw vulcanite, which, on the mold being reclosed, is subjected to the usual process of vulcanizing.

The foregoing description comprehends most of the operations connected with surgical and mechanical dentistry. For a more detailed account of them, as well as the discussion of many minor points connected with the subject, we must refer to the numerous and beautifully illustrated works specially devoted to such matters, lately published both in this country and America; of these, Mr. Tomes of London's *Dental Surgery*; Dr. Smith of Edinburgh's *Handbook of Dental Surgery*, published by Churchill, London; Taft's *Operative Dentistry*, and Richardson's *Mechanical Dentistry*, both published in America; Oakley Cole's *Dentistry*; etc., deserve to be specially mentioned as among the latest and best works on the subject.

**DENTITION, PERIOD OF** (Lat. *dentitio*, the process of teething, from *dens*, a tooth). In man and most mammals, there are two distinct sets of teeth; one set which appears shortly after birth, and which are termed the *milk* or *deciduous* teeth; and a second set, which, after a few years, replaces these, and which are termed *permanent* teeth.

In the human subject, the milk-teeth are twenty in number, each jaw containing (from before backwards) four incisors, two canines, and four molars; while the permanent teeth are thirty-two in number, each jaw containing four incisors, two canines, four premolars or bicuspsids, and six molars. Anatomists are in the habit of briefly expressing the number of the different kinds of teeth in any mammal by what they

term a *dental formula*. The permanent teeth in man are represented by the formula,  $i \frac{2-2}{2-2}, c \frac{1-1}{1-1}, p \frac{2-2}{2-2}, m \frac{3-3}{3-3} = 32$ , where the letters *i*, *c*, *p*, *m*, stand for incisors, canines, premolars, and molars, and where the two terms in each numerator and in each denominator represent the number of each particular kind of tooth in each half of the upper and lower jaw respectively. As these formulæ are of common use in most works on zoology and comparative anatomy, we add another example—that of the permanent teeth of the hog, whose formula is  $i \frac{3-3}{3-3}, c \frac{1-1}{1-1}, p \frac{4-4}{4-4}, m \frac{3-3}{3-3} = 44$ : which signifies that there are on each side of both upper and lower jaws three incisors, one canine, four premolars, and three molars, making in all 44 teeth.

For a general description of the form and uses of these different kinds of teeth, we refer the reader to the article DIGESTION, ORGANS AND PROCESS OF, where their special uses are noticed in reference to the digestive function; while the history of their structure, etc., is given in the article TEETH.

The following is the usual order and period of appearance of the milk-teeth: The four central incisors usually appear through the gums about the seventh month after birth, those of the lower jaw showing themselves first. The lateral incisors next appear between the 7th and 10th months; the anterior molars show themselves about the 13th month, and are soon followed by the canines, which usually appear between the 14th and 21st months. The posterior molars are the last and most uncertain in their time of protrusion, which may range from the 18th month to the end of the 3d year. Except in the case of the incisors, there is no definite law as to whether the upper or lower teeth first appear.

About the middle or end of the 7th year, the jaw-bones have become sufficiently elongated to permit the appearance of the first true molar; and about the same time, the central incisors are replaced by the corresponding permanent teeth. The advance of the permanent teeth towards the surface of the gum causes the absorption of the roots of the temporary teeth, and thus facilitates their shedding; the crown falling off, and leaving room for the permanent tooth behind it to come forward and supply its place.

In the replacement of the first by the second set of teeth, the following order is observed: The middle incisors are first shed and renewed (usually when the child is about eight years of age), and then the lateral incisors (perhaps a year later). The anterior molars of the first set are then replaced by the anterior premolars (this usually happens about the 11th year); and about a year afterwards the posterior deciduous molars are replaced by the second premolars. The persistent canines take the place of the deciduous ones in the 12th year; these being the last of the milk-teeth to be exchanged. The second molars appear between the ages of twelve and a half and fourteen years; and the third molars, or *dentes sapientie* (wisdom teeth), seldom appear till three or four years subsequently, and often much later.

The factory laws in England render it very important that we should be able to determine the ages of *nine* and *thirteen* in children, because before a child is nine years old, it is illegal to employ it in factory-work; and until it is thirteen, it may only be employed for a limited number of hours a day. Mr. Saunders, a well-known dentist, has shown in his pamphlet, *The Teeth a Test of Age, combined with Reference to Factory Children*, that the teeth afford a far better test of age at this period of life, than the standard of height which has been adopted by the legislature for this purpose.

*Dangers attending Teething.*—The teeth are formed in closed sacs, and in rising to the surface in the progress of their growth they slowly penetrate the gum from below; a process familiarly called "cutting the teeth." The minuter physiology of this process will be described in a separate article (see TEETH); in the present it will be sufficient to indicate shortly the dangers to which children are exposed, particularly during the period of the first dentition, or from five months old to two years or more. Infants are occasionally said to die of "teething;" but this, like many other vague terms, may be said to be only a cloak for ignorance; for the mere cutting of the teeth is never, by itself, mortal, or even a serious source of suffering. It only becomes a cause of disease by its reflected influence on the delicate nervous system of the child. The period of dentition, in fact, is one during which the whole organization of the infant is undergoing a revolution; in passing from an exclusively milk-diet to one of a more complex character, the entire digestive system undergoes a corresponding development. The diseases of this period of life correspond in importance with the great physiological changes taking place in it, and with the dangers of derangement in the just order or symmetry of their development. If these diseases often appear to be due directly to the cutting of a tooth, it is because complex causes of disorder have prepared the way for a morbid change, which is ready to be developed into activity by a comparatively slight irritation. The principal diseases of dentition are diarrhea (q.v.), convulsions (q.v.), vomiting, and hydrocephalus, or tubercular inflammation of the membranes of the brain, which are all apt to originate at this period of infantile life, and to coincide more or less closely with the development of the first set of teeth. It is very doubtful how far the operation of cutting the gum with a lancet, so commonly supposed a specific for the diseases of dentition, ought to be encouraged. Sometimes there is evident irritation,

or even inflammation of the gum, and then the operation will probably at least do no harm; but the indiscriminating use of the gum-lancet, at the request of anxious but foolish mothers and nurses, is characteristic of a weak and erroneous routine practice, and must be denounced as an unwarrantable interference with the truly beautiful process by which the tooth is gradually evolved from its socket, in most cases without any suffering. The special treatment of the diseases of dentition is discussed under the separate articles devoted to some of these diseases.

**DENTON**, a co. in n.e. Texas, on the upper waters of Trinity river; 900 sq.m.; pop. '70, 7,251—510 colored. It is a prairie and forest region. Agriculture is the chief business. Co. seat, Denton.

**D'ENTRECASTEAUX**, a term of various application in Australasia, affords one of the few traces of French discovery in that part of the world. It indicates an archipelago, a cape, and a channel.—1. The archipelago lies between New Guinea and New Ireland, about lat.  $10^{\circ}$  s., and long.  $151^{\circ}$  e.—2. The cape, a headland in West Australia, forms nearly the s.w. point of the continent, being in lat.  $34^{\circ}$  52' s., and long.  $116^{\circ}$  e.—3. The channel, an arm of the Pacific, separates Bruné island from the s.e. coast of Tasmania or Van Dieman's land. It is about lat.  $43^{\circ}$  25' s., and long.  $147^{\circ}$  15' e., is 35 m. long, and varies in width from 3 to 9 miles. On the side of the mainland, it is connected with the interior by means of the Derwent and the Huon, communicating through the former with Hobart-town, the capital.

**DENUDATION** is the removal of solid matter by water in motion, whether of rivers or of the waves and currents of the sea, and the consequent laying bare of some inferior rock. The rate of abrasion depends upon the velocity of the current, and the nature of the solid materials through which it flows; these two causes equally affect the deposition of the abraded matter, for the carrying power of the water varies with its velocity and with the weight of the particles. The heavier débris—large stones and gravel—are carried short distances, and deposited generally in masses; the finer particles are conveyed even by a slow current to great distances, and scattered in thin layers over extensive districts. All deposition, except in the case of showers of volcanic ashes, is the sign of a superficial waste going on contemporaneously, and to an equal extent, elsewhere, the gain at one point being equal to the loss at another. No new material has been used in the formation of the sedimentary rocks. The degradation and abrasion of igneous rocks provided the materials of the earliest strata: these in their turn were frequently abraded and re-deposited, under new conditions, and with the remains of a newer fauna and flora. Thus the crust of the globe has not actually increased in thickness, for whenever it acquires density in one place, it becomes thinner in another. The changes that have been effected by D., and the amount of matter thus transported, are difficult to imagine. In districts where faults occur, the surface has been smoothed, and the uplifted ends have been washed away. These faults sometimes extend over several hundred sq.m., and the dislocations, had they remained unaltered, would have produced mountains with precipitous escarpments of different heights, reaching occasionally to a thousand feet. But D. not only leveled the surface of the earth; in regions with horizontal stratification it has produced inequalities, hollowing out valleys of D., and often carrying away the whole of the superficial strata, leaving mountains here and there which show, by the direction and succession of their beds, that the strata of which they are composed were at one time continuous.

**DENVER**, the capital of Colorado, in Arapahoe co., on the South Platte river, about 15 m. from the eastern base of the Rocky mountains, at the junction of the Kansas Pacific, Denver Pacific, Colorado Central, and Denver and Rio Grande railroads, 620 m. w. of Omaha; pop. '70, 4,759; '80, about 35,718. The city, 5,375 ft. above the sea, occupying a series of levels rising gradually towards the mountains, commands a magnificent view of the nearer plains and of peaks covered with perpetual snow. Its climate is delightful. It is the commercial as well as the political capital of the state, and has had wonderful growth. There are many manufactories, smelting and refining works, a United States mint, and various public buildings. In 1858, there was not a human habitation in the vicinity.

**DEOBSTRUENTS** (Lat. *de*, from, and *obstruo*, I obstruct), medicines which have the property of removing obstructions, especially in the lymphatic system (q.v.). The glands of the thorax and abdomen (e.g., the liver, spleen, kidneys, etc.), as well as the lymphatic and lacteal glands, are subject to enlargements, which were formerly, under a mechanical theory of disease, universally ascribed to obstructions of their outlets, or of the vessels in connection with them; against all of these states, D. were employed with varying success. The favorite deobstruent remedies are mercury, iodine, and bromine; blisters and friction, with stimulating liniments, may be said also to have a like action in some cases.

**DEOBUND**, a t. of India, in the British district of Saharunpore, North-west Provinces, 20 m. s.e. from Saharunpore, on the railway route from Saharunpore to Mozuffnurgur. It is situated between the rivers Hindun and Kali Nuddee, the one a branch of the Jumna, the other of the Ganges, in an open cultivated country. Pop. '72, 19,168.

**DE'ODAND.** A personal chattel which was the immediate and accidental occasion of the death of a reasonable creature, was, by the law of England, forfeited to the crown, in order that it might be applied to pious uses, or given to God, as the term implies. The rule did not apply where the instrument had been intentionally used for the purpose of causing death, as in cases of murder and homicide. Blackstone traces the origin of the custom to the popish prayers for the souls of the dead, and asserts that deodands were "designed in the blind days of popery, as an expiation for the souls of such as were snatched away by sudden death; in the same manner as the apparel of a stranger, who was found dead, was applied to purchase masses for the good of his soul." The more probable view is, that it originated in the natural horror which is felt for whatever has been the instrument of so dreadful an occurrence; just like the Jewish law, that if "an ox gore a man that he die, the ox shall be stoned, and his flesh shall not be eaten;" or the old English law, that a well in which a person was drowned should be filled up under the inspection of the coroner. Similar regulations are to be found in the legal systems of most nations. The law of deodand was abolished by statute 9 and 10 Vict. c. 62.

**DEODAR.** See CEDAR.

**DEODAR**, remarkable as being one of the pettiest states in the world, is a district in the n.w. of Guzerat. Containing only 80 sq.m., and 2,000 inhabitants, it is yet subdivided into as many independent communities as there are villages—the whole being, for external purposes, under the gratuitous protection of the British government. The principal village, bearing the name of D., is in lat. 24° 9' n., and long. 71° 49' east. The district was forced on the East India company in 1819, as having become a refuge of marauders.

**DEO DORIZERS** are chemical substances employed for the purpose of absorbing or destroying the odoriferous principles evolved especially from decomposing animal and vegetable matter. They strictly belong to the classes of substances known as antiseptics (q.v.) and disinfectants (q.v.).

**D'ÉON, CHEVALIER.** See EON, DE BEAUMONT, *ante*.

**DEORI**, sometimes distinguished as BURA DEORI or GREAT DEORI, a t. of Hindustan, stands in lat. 23° 22' n., and long. 79° 4' e., and is 1705 ft. above the level of the sea. Though it has been but little noticed by travelers or writers, yet it appears to be not unworthy of its second name, as mentioned above, for, on its being burned down by a freebooter before English authority was established here, 30,000 people are said to have perished in the flames. Pop. '72, 5,500. It is situated in the Nagpore division of the central provinces, on the table-land, whence flow the Sone to the Ganges, and the Nerbudda to the Arabian sea; so that the territory of Saugor and Nerbudda, within which it is contained, is common to the two principal basins of northern India. The place is about half-way between the better known cities of Saugor and Gurrah, being 44 m. to the s.e. of the former, and 41 to the n.w. of the latter.

**DEOXIDA TION** is the term applied to the process of withdrawing the oxygen from a compound, as in the reduction of the native peroxide of iron in the smelting furnaces to the condition of metallic iron. On the small scale, in experimental inquiries, the process of deoxidation may be carried on before the blow-pipe (q.v.), where the inner or reducing flame is essentially a deoxidizing one.

**DEPARTMENT** (Fr. *département*), a term used to denote a territorial division in France. Previous to the revolution, France was divided into provinces; but in 1790 Mirabeau rose in the constituent assembly, and declared that, after having abolished aristocracy, it was neither convenient nor safe to preserve these provincial divisions. He alleged that they were too large, that they tended to concentrate the administrative power in the hands of a few, and that such power soon becomes aristocratic of necessity. He suggested, therefore, a ministerial territorial division, as a carrying out of the principles of the revolution. This expression of opinion was followed by a decree of the assembly, dated Feb. 16, 1790, ordering the abolition of the old provincial divisions (34 in number), and the redistribution of the land into 83 departments. During the year 8 of the revolution, these were increased to 98; in 1808 the empire consisted of 127; at the fall of Napoleon, of 130; and at present it consists of 87, including the sadly diminished department of Haut Rhin (from 1871 till 1879 "the territory of Belfort"). Originally, it was intended that the departments should be governed by persons elected by the citizens; but this plan did not suit the views of the first consul, who placed over each department a prefect, and a *conseil de préfecture*. The departments were again subdivided into arrondissements, over each of which was placed a sub-prefect (*sous-préfet*). The right of naming these functionaries was reserved to the chief of the state. This system of departmental administration is still in force in France.

**DEPARTMENT** is a word used to designate a subdivision of executive government, under the control of a subordinate officer. In the United States, e.g., there are the departments of state, justice, interior, war, navy, treasury, post-office, and agriculture. In some of these departments the work, according to its character, is distributed between different bureaus. The government itself is conducted in three separate departments, each independent in its sphere, viz., the legislative, the judicial, and the executive. The

country is also subdivided into military departments, each under an officer appointed by authority of the president.

**DEPARTURE**, a term in navigation, explained under **SAILINGS**. See also **DEAD RECKONING**.

**DEPENDING ACTION**. An action is said in Scotland to be in dependence, from the moment of citation, until it be finally decided by the house of lords, should it be appealed to that ultimate tribunal. As a security for the implement of the decree by the defender, in the event of his being found liable, the pursuer is entitled to use either inhibition (q. v.) or arrestment (q. v.) on the dependence, or depending issue.

**DE PERE**, a t. in Brown co., Wis., on Fox river, and the Wisconsin Central, and Chicago and Northwestern railroads; pop. '70, 3,834. There are two villages on opposite sides of the river connected by a bridge of 1500 feet. The Milwaukee and Northern railroad passes along the river. In the villages are many manufactories.

**DE PEYSTER**, ARENT SCHUYLER, 1736-1832; an English soldier, native of New York, holding command at Michilimacinae; through whose exertions the Indians very generally sided with the British during the revolutionary war. Late in life he resided in Dumfries, Scotland, and was on terms of friendship with Robert Burns, who was a private in De P.'s regiment of volunteers, and with whom he carried on a poetical controversy in a newspaper. Burns dedicated to him his *Poem on Life*. He was a commissioned officer in the British army for 77 years.

**DE PEYSTER**, JOHANNES, d. 1685; one of the early settlers of New York, and founder of a noted family. He was a French Huguenot. In New York he filled many offices, including that of mayor.

**DE PEYSTER**, JOHN WATTS, b. New York, 1821; descendant of Johannes; a writer on military and historical subjects; author of *Life of General Torstensen*; *The Dutch at the North Pole*; *The Dutch in Maine*; *Early Settlement of Acadia by the Dutch*; *The Dutch in the Battle of the Baltic*; *History of Cæsar*; *The Ancient, Medieval, and Modern Netherlands*; *Winter Campaigns the Test of Generalship*; *Practical Strategy*; *Secession in Switzerland and the United States Compared*; *Decisive Conflicts of the late Civil War*; etc. De P. was active in introducing a paid fire department in New York. His three sons, J. Watts, jr., Frederick, jr., and Johnston L., were gallant officers of the union army in the war of the rebellion.

**DEPHAL**, *Artocarpus lakoocha*, a tree of the same genus with the bread-fruit (q. v.) and jack (q. v.), a native of the s. of India, and frequently cultivated in the northern parts of that country. The fruit is eaten, but is inferior to the jack. The juice, like that of the bread-fruit, is tenacious, and is used for bird-lime. The root is used for dyeing yellow. The D. is a large tree, and its timber is valued for a variety of purposes.

**DEPHLOGISTICATED AIR**. See **PHLOGISTON**.

**DEPILATORIES**, or **EPILATORIES** (Lat. *depilo*, to pull out the hair), are chemical agents employed for removing superfluous hair from the skin. They were extensively used by the ancients, but are now restricted in their employment to the face, and to the removal of the hair from the scalp in the treatment of certain diseases. The caustic alkalies and alkaline earths are generally used, and a good recipe is to mix 5 parts of caustic or slaked lime, 10 parts of carbonate of soda, and 40 parts of lard. The tersulphuret of arsenic (commonly known as orpiment) is occasionally used, but its employment is dangerous, as any abrasion of the skin will enable the arsenical compound to begin to act. A mixture of caustic lime and orpiment constitutes some of the depilatories to be purchased; and it is believed that the Turkish *rusma* is composed of these ingredients. A very active and comparatively safe compound is a strong solution of sulphuret of barium made into a paste with starch, which is immediately applied to the part from which the hair is to be removed, and is allowed to remain for five or ten minutes.

**DEPLOY**, as a military movement, is a spreading out of a body of troops in such way that it shall display a wider front and a smaller depth than it did before the deploying.

**DEPO NENT**, a term in Latin grammar applied to verbs having a passive form but an active signification. They are so called because they, as it were, lay down (Lat. *depono*) or dispense with the signification proper to their form. Such verbs had all originally a reflective meaning, like the middle voice in Greek verbs; thus, *aversor*, "I detest," means radically, "I turn myself away from."

**DEPORTATION**, the forcible removal of a people from their country; in former times employed as a means of securing the fruits of conquest. In the Scriptures it is recorded that not only the Jews, but other peoples were carried away captives. Banishment is still a method of punishing political offenders in France and some other countries.

**DEPOSIT** was a real contract of the civil or Roman law. It was the simplest of all contracts, and consisted merely in the delivery of an article by one person to another,

to be kept without remuneration, and to be restored *in specie* as soon as the depositor should require.—*Inst.* iii. 15, s. 3. Return when required was the sole condition of the contract; and no obligation was incurred by the depositary but to exercise ordinary care in preservation of the article. The civil law recognized a distinction, as to the value which might be recovered by the depositor in case of loss, between the case of articles voluntarily deposited, and those which came into the hands of the depositary by the misfortune of the owner, as by fire or shipwreck. In the latter case, double the value of the article might be recovered. There was also a special provision by the edict *Nautæ, cauponæ, stabularii*, whereby shipmasters, innkeepers, and stablemen were compelled to exercise more than ordinary vigilance over the goods of their customers and passengers.

The principles of the civil law as to D. have been universally adopted by modern nations. In Scotland, the name of the contract is preserved. Lord Stair, i. 13, 2, lays down that the depositary is "not liable for light faults, or for the perishing or deterioration of the thing deposited by casualty or accident." The article must be restored when demanded, and failure to do this will involve the depositary in liability for the consequences. See also Erskine, iii. 1, 26.

Deposit, in English law, is a branch of bailments, which includes also loans, pledges, and letting and hiring. From each of these, D. is distinct. It is defined by judge Story to be "a bailment of goods, to be kept by the bailee without reward, and delivered according to the object and purpose of the trust."—*Story on Bailments*, c. ii.

The chief questions which have arisen in modern times relate to the amount of care which the depositary is bound to exercise. Judge Story lays down the principle to be, not the care which a man takes of his own affairs, but that which a reasonable being would use, and cites in support of his view the case *Doorman v. Jenkins*, ii. Ad., and *Ellis* 256, where a person intrusted with money placed it in his own cash-box, and the box having been stolen, the depositary was yet held liable for negligence. So also with jewels or other valuables—the nature of the article implies extra care. Where, however, a sealed packet or locked box is deposited, the question arises as to the liability of the depositary. Erskine lays it down broadly, that where such a deposit is made without showing the contents, the depositary incurs no extra liability. But Story takes a distinction, and states that if the depositary had reasonable ground to believe the contents were valuable, he incurs liability accordingly. The immense value of the timber-trade of America raises in that country questions as to the liability of a landowner for timber left by the river on his ground. On this point, Story indicates that the smallest amount of liability is incurred. Whether or not the depositary may make use of goods left in his charge, is said by the same author to depend on the particular circumstances. If the article would benefit by use, then such use is allowable; but if injury were likely to accrue, it is not. If use is a matter indifferent, then the depositary is not entitled to the use. The admirable work of Story on Bailments is the best authority on this subject.

**DEPOSIT**, a term much used in geology, to characterize those rocks which have been formed from matter that has settled from suspension in water. The materials constituting such rocks have been obtained by denudation, and their extent in one place equals the denudation in some other. Deposits are characterized according to the conditions under which they were formed, as marine, lacustrine, fluvatile, and so forth.

**DEPOSITION**, the testimony of a witness set down in writing. Depositions are taken either by a judge or by a commissioner specially appointed by him for that purpose. The questions to which the depositions are answers are usually put by the legal representatives of the parties to the suit, under the control of the court or commissioner, and the answers are taken down by the clerk of court, or by a clerk specially appointed for the purpose. If the competency of the questions or the admissibility of the witnesses be objected to, the objection must be stated to the court or commissioner. The latter may either dispose of the objection at the time, or reserve it for the opinion of the court by which he was appointed. It is a rule in the laws of evidence of all countries that the deposition cannot be read where the witness might be himself produced, because his oral testimony is the best evidence, and secondary evidence is never admissible. Where he is dead, however, or insane, or beyond the jurisdiction of the court, his deposition then becomes the best evidence, and may be read in court.

**DEPOSITION OF A CLERGYMAN.** In Scotland, the minister of a parish who has been guilty either of immoral and scandalous conduct, or of preaching or otherwise publishing doctrines contrary to the standards of the church to which he has declared his adherence, or of contumaciously setting aside the authority of the Presbyterian church-courts, may be deposed from his holy office by the church-courts. By this means he is deprived not only of his ecclesiastical dignity, but of the temporalities of his benefice (stat. 1592, c. 115), and the benefice becomes vacant, just as if he were dead. He may, however, be restored to the exercise of the ministry, and to his position as a minister of the church by the general assembly, but he cannot, of course, be restored to his benefice; and it is considered irregular that he should be so even by a new presentation by the patron, because the stigma attached to his character by his deposition is likely to affect his usefulness. Where sentence of deposition is pronounced by an inferior church-court, the judgment of which is reversed on appeal to the general assembly, it is

held that it has never been pronounced; but if the sentence be affirmed, it takes effect from the date when it was pronounced by the inferior court, and from that date the minister's right to the profits of his benefice ceases. Sentence of deposition cannot be pronounced by a presbytery in the absence of the minister, except by the authority of the general assembly. See DEPRIVATION OF A CLERGYMAN.

**DEPOT**, in military matters, is a name sometimes given to a place where army stores are deposited during war. In the regimental system, however, a depot used to be the town or barrack where certain stores belonging to the regiment were kept, as well as the regimental books and some of the men, when the regiment was ordered on foreign service. It was rarely that a whole regiment was engaged in active service at once; either one or two companies were generally kept at home, under the command of one of the officers, and were called *depot companies*. They formed a nucleus where recruits were received and drilled, and where the corporate existence of the regiment might be kept up. By the military forces localization act of 1872, under which the United Kingdom is divided into 70 sub-districts, every battalion, whether at home or abroad, has a depot of two companies. The depots of two battalions constitute the depot-center, or sub-district brigade, to which the volunteers and militia of the sub-district are affiliated. In time of war, the depot would expand into a third battalion.

**DEPPING**, GEORGES BERNARD, 1784-1853; a native of Westphalia, resident of Paris; a writer on a wide range of subjects. Two of his juvenile works attained wonderful popularity: *Winter Evenings*, including the instructions of a father to his children on moral and scientific themes; and *Beauties and Marvels of Nature in France*. He assisted Malte-Brun in his geographical works, and wrote a number of important histories, books of travel, biographies, etc.

**DEPRÈS**, or **DESPREZ**, JOSQUIN, 1440-1521; a French musical composer, of whose life little is known. He was considered by his contemporaries to be the greatest master of his age. Luther was among his admirers. His works consist chiefly of sacred music.

**DEPRESSION** or **DIP OF THE HORIZON** is the angle through which the sea-horizon appears depressed in consequence of the elevation of the spectator.

Let A be a point on the surface of the earth, B a point situated in a vertical line from A. Let BH be a tangent to the earth's surface drawn from B, B*h* a line in the same vertical plane perpendicular to AB. The angle *h*BH is the *true dip* of the horizon to a spectator at B.

The true dip measured in minutes is equal to the distance in nautical miles of the visible horizon. Let C be the center of curvature of the surface; then, since CHB is a right angle, the angle *h*BH = HCA; and the minutes in this angle are the nautical miles in the arc AH. To find this angle in minutes or nautical miles, the rule is: Multiply the square root of the height in feet by 1.063.

The true dip of the horizon, however, is not exactly the same as its apparent depression. The apparent sea-horizon is raised above its true place by *refraction* through an angle, which varies according to the state of the atmosphere and the relative temperatures of the air and water, the variation ranging from one third to one twenty-third of the amount of the true dip. The rule commonly employed is to diminish the true dip by about one fourteenth of its amount, to find the apparent dip.

If S be a star or the sun in the same vertical plane with ABH, and an observation of the altitude above the sea-horizon be made by means of a sextant from the point B (as from the deck of a vessel), the apparent dip of the horizon must be subtracted from the observed angle, in order to find the altitude of the sun. Owing to the uncertainty of the amount of refraction, the nearest minute to the dip given in the tables is usually taken. The following table gives a sample of the amount of the apparent dip under ordinary state of the atmosphere and equal temperature of air and water. See Raper's *Practice of Navigation*.

Height. Feet.	Dip. m. s.	Height. Feet.	Dip. m. s.
0.....	0 0	8.....	2 50
1.....	1 0	9.....	3 0
2.....	1 20	10.....	3 10
3.....	1 40	20.....	4 20
4.....	2 0	30.....	5 20
5.....	2 10	40.....	6 10
6.....	2 20	50.....	7 0
7.....	2 40	100.....	9 50

**DEPRIVATION OF A CLERGYMAN.** In England, this may be either (1.) by a sentence declaratory in the proper court, on the ground of attainder or conviction of treason,

felony, or any other inamous crime, or of conviction for heresy, infidelity, or gross immorality, or for farming or trading contrary to law, 1 and 2 Vict. c. 106, s. 31; or (2.) in pursuance of divers penal statutes, which declare the benefice void for some nonfeasance or neglect, or else some malfeasance or crime, as simony; for maintaining any doctrine in derogation of the king's supremacy, or of the thirty-nine articles, or the book of common prayer; for neglecting to read the liturgy and articles in the church, and to declare assent to the same, within two months after induction; for using any other form of prayer than the liturgy of the church of England; for continued neglect, after order from the bishop, followed by sequestration, to reside on the benefice. In these latter cases, the benefice is void, without any formal sentence of deprivation (Stephen's *Com.*, iii. 37). A bishop may be deprived of his bishopric, but cannot be deposed, as may be done in the case of a Presbyterian clergyman, the character of a bishop, like that of a priest, being indelible. The tribunal by which the bishop of Clogher was deprived in 1822 consisted of the archbishop and the other bishops of the province; and this precedent having been established, would probably be adhered to on any future occasion, notwithstanding that the archbishop alone might have full authority to deprive.—*Cripps's Laws of the Church*, p. 100.

**DE PROFUNDIS** ("Out of the depths"), the first words of the 130th psalm, which forms a portion of the liturgy of the Roman Catholic church, and is sung when the bodies of the dead are committed to the grave. A tender melancholy pervades the psalm, which, however, brightens up at the close under the conviction that with God there is "plenteous redemption."

**DEPTFORD**, a t. on the s. bank of the Thames, about 4 m. below London bridge, divided from Greenwich by the river Ravensbourne, a creek of deep water (*depe, ford*), formerly fordable at the spot where D. bridge now stands. It contains two parishes, St. Nicholas' and St. Paul's, the latter formed by act of parliament in 1727. St. Nicholas' Deptford lies wholly in Kent, but St. Paul's extends into Surrey—the Surrey portion being known as the Manor of Hatcham. Pop. in 1871, 60,215, engaged to a large extent in the royal Deptford victualing-yard, and in extensive private ship-building and engineering establishments. The market-gardens of Deptford are famous. The upper portion of the town is well built, and is a favorite place of residence for persons engaged in business in London. D. forms, with Greenwich, Woolwich, Charlton, and a portion of Plumstead, the parliamentary borough of Greenwich, which returns two members. The ancient incorporation of the master and brethren of the Trinity house of "Deptford Strand," founded by Henry VIII., has its hall at D., and also two sets of almshouses. Queen Elizabeth, in 1581, visited Drake at D., in the ship in which he "compassed the world." In 1698, Peter the great acquired the art of ship-building in the dock-yard here, residing at the manor-house of Sayes court, which John Evelyn had previously occupied.

**DEPTFORD DOCK-YARD**, as one of the royal naval establishments, was not so remarkable for ship-building as for other operations connected with the fitting-out of fleets. Being ill adapted for the large war-ships of the present day, the dock-yard proper was abandoned in 1855, and the naval establishment limited to the victualing-yard, an important place, employing several hundred persons as officers, clerks, workmen, and hoymen. This is the chief depot for victualing the home and foreign stations, and the marines; also for slops and many of the necessaries for seamen. It is convenient for these purposes in being near the metropolitan markets. The officers receive, examine, store, pack, reissue, and register the various stores, and transmit all their accounts to the admiralty. For simplicity it used to be called collectively a royal dock-yard; but the ship-building, the store-keeping, and that very miscellaneous process called the provisioning, were the work of different establishments.

**DEPUCH ISLAND**, a member of the Dampier archipelago, lies off the n.w. coast of Australia, in lat. 20° 38' s., and long. 117° 44' east. Though only 8 m. in circuit, yet it is, on more than one ground, worthy of notice. On it have been found some curious specimens of native sculpture; and, rising with its greenstone rocks to a height of 514 ft. above the sea, it presents a remarkable contrast to the low-lying shore of the adjacent mainland.

**DEPUTY**, one who exercises power which properly belongs to another who has placed him in his stead. The appointment of a deputy does not free the principal from responsibility, for the deputy is not an assignee. It is a general rule, that no judge can appoint a deputy unless he be authorized to do so in the commission by which he himself is appointed. In the rare cases in which a deputy is empowered to appoint a deputy, the latter is usually called a substitute. See **SHERIFF**.

**DE QUINCEY**, THOMAS, a distinguished English writer, was b. in Manchester, Aug. 15, 1786. His father was a wealthy Manchester merchant, who, dying while his children were yet young, left his widow a fortune of £1600 a year. De Q. received his first education at home, and was afterwards sent to the grammar school of Bath. He proceeded to the university of Oxford in 1803, and remained there till 1808. At the university, he made the acquaintance of opium, which was ever afterwards his dread familiar. On leaving college, he went to reside at the lakes, and formed one of the

cluster of literary lights which made that region at the time so illustrious, and afterwards so memorable. He left Cumberland in 1819; and in 1843, he came to reside in Scotland, settling with his family at the village of Lasswade, near Edinburgh. He died at Edinburgh on the 8th Dec., 1859.

With the exception of a strange episode of his youth, described in the *Confessions of an Opium-eater*, the heroine of which was, singularly enough, one of the "waifs of womanhood," De Q.'s career was almost entirely eventless. He led a lonely and a speculative life, and his writings are at once history and autobiography. He was perhaps, with the exception of his friend prof. Wilson, the most brilliant magazine-writer in this century of magazines. Everything he wrote, putting aside the *Confessions*, *The Logic of Political Economy*, and a novel, which no one seems to have read, or, if read, to have remembered, is in the form of articles. Even the *Confessions* themselves were originally published as a series of articles in the *London Magazine*. De Q. has written on a great variety of subjects, and in a great variety of styles. He has written articles pervaded by humor of the most curious and novel kind, philosophical and critical articles distinguished by originality and daring of speculation, and articles of the nature of prose-poems, which are unquestionably of their kind the most wonderful things in English literature. In point of imaginative grandeur, and music and sweep of sentence, the *Suspiria de Profundis*, and the opium visions that close the *Confessions*, are miracles of impassioned prose. De Q.'s works were first collected and republished in America. The edition of De Q.'s works, in 16 vols., published by A. & C. Black, Edin., includes nearly all his writings. See Page's *Life and Writings of De Q.* (1877).

**DERAH**, the Egyptian unit measure of length. The one most in use is 22.37 English in., or 57 centimeters. The derah is divided into the *karlam*, one half; the *abdat*, one sixth; and the *kerat*, one twenty-fourth. The derah by which dry-goods are sold is  $20\frac{1}{2}$  in., and the derah of Constantinople is 66.34 inches.

**DERAJAT'**, the fluvial portion of Daman (q.v.), itself a comparatively narrow strip in the Punjab, between the Suliman mountains and the Indus, and which, when duly irrigated, is singularly fertile. D. is so called from *dera*, a camp, a common element in the names of its towns—Dera Deen Punah, Dera Futti Khan, Dera Ghazee Khan, and Dera Ismail Khan. It is divided into three districts, and has an area of 12,565 sq. m., and a pop. of 991,251. Dera Deen Punah, apparently the least considerable of the above towns, has suffered much from physical causes, having, in 1819, been nearly destroyed by an earthquake and by a simultaneous flood from the Suliman mountains. —Dera Futti Khan is the center of a district which produces cotton, grain of various kinds, indigo, sugar, and opium. Pop. 5,900.—Dera Ghazee Khan occupies, for commercial purposes, a very favorable position—the intersection of the two great routes of the country between n. and s., and between e. and west. Hence it has been recommended as the best site for an annual fair, so as to suit at once Sind, the Punjab, Afghanistan, Beloochistan, and Khorassan. It manufactures cotton, silk, and steel, and has an extensive bazaar. Pop. 17,164.—Dera Ismail Khan is of recent origin, another town of the same name having been swept away by an inundation of the Indus. It stands on the thoroughfare already mentioned between n. and s., commanding also two ferries across the river. To this position it is indebted for a thriving trade, and in spring particularly it is crowded by the Lohani Afghans, an enterprising tribe of pastoral peddlers. Pop. 24,906.—Besides the towns already described, D. has Isa Khel, a town with (1872) 17,746 inhabitants; and the important commercial town of Leia (q.v.).

**DERA'YEH**, or DEREY'EYAH, a t. of Arabia, formerly the capital of the Wahabees. It is situated near the center of Nedjed, 430 m. n.e. from Mecca. It was a town of some consequence before the time of the Wahabees, but attained its highest importance under their dominion. See WAHABIS. It was taken by Ibrahim Pasha in 1819, after a siege of seven months, and nearly destroyed. It stands in a valley about half a mile in breadth, filling the whole breadth of the valley, and may probably have at one time contained 40,000 inhabitants, whereas now its pop. is not estimated at more than 15,000.

**DERBEND'**, or DERBENT', a t. of Russia, capital of the government of Daghestan, is situated on the western shore of the Caspian sea, on the declivity of a branch of the Caucasus, which here approaches very close to the water's edge, and forms a defile anciently known as the *Albanic Pyle*, now called the Pass of Derbend. Lat. 42° n., long. 48° 15' east. D. is built in the form of a parallelogram, being about 3 m. in length, and from a quarter to half a mile in breadth. It is surrounded by strong walls of very ancient date, which are further strengthened at intervals by towers. From two massive iron gates, through which the road to the interior passes, the town derives its name, which signifies "the shut-up gates." The harbor of D. is quite inaccessible to all but small boats. The manufactures of the place consist chiefly of coarse silk and woolen stuffs, and saffron is cultivated. Pop. '67, 15,739. D. is a very ancient place, having, as it is said, been fortified by Darius I. to prevent the incursions of the Scythians; and it was long considered the key of Persia on the n.w. side. It came finally into the possession of Russia in 1795.

**DERBY**, a t. in New Haven co., Conn., on the Housatonic river at the mouth of the Naugatuck; pop. '70, 8,020. The place is reached by the New Haven and Derby and

the Naugatuck railroads, and is approached by vessels drawing 10 ft. of water. It contains the villages of Birmingham and Ansonia.

**DERBY**, a parliamentary and municipal borough and manufacturing town, the capital of Derbyshire, in the s. part of the co., in the wide and fertile valley of the Derwent—thence navigable to the Trent—at the junction of the main branches of the Midland railway, 132 m. n.w. of London, and 35 m. n.e. of Birmingham. The houses are mostly of brick, and the public buildings of stone. The free grammar-school is one of the oldest English foundations, reaching to 1162. Here Blackwell, author of the *Sacred Classics*, was a master, and Flamsteed a pupil. Dr. Darwin, in 1783, founded the philosophical society of D., and wrote most of his works here. D. is well situated for manufacture and trade, being at the s. end of a coal-field, and being connected by canals and railways with a great part of England. It has manufactures of silk, cotton, lace, hosiery, lead, iron, paints, porcelain, jewelry, black marble vases, columns, chimney-pieces, and ornaments of fluor-spar, petrifications, marble, etc. The staple manufacture is throwing silk, introduced by Mr. Crochet from Italy early in the 18th c.; the silk-mill, with machinery still in use, erected in 1718 by John Lombe, being the first and largest of the kind in England. Pop. (1871), municipal borough, 49,449; parliamentary borough, 61,381. D. returns two members to parliament. In 1867, a new cattle-market, on a very complete scale, was opened, and also a new corn-exchange. The grammar-school was removed in 1862 from St. Peter's church-yard to St. Helen's house, the site of the original foundation; and a large handsome market-hall was completed in 1866. In 1867, Mr. M. T. Bass, for nearly forty years one of the members of parliament for D., presented the town with six acres of recreation ground; and a new wing was added to the general infirmary. D. was the Roman station *Derwentio*, which stood on the e. bank of the river, opposite the town. Roman brass, silver, and gold coins have been found, a Roman pavement, and the foundations of a Roman bridge. D.—called *Northcorthrige* by the Saxons, and *Deoraby* by the Danes—was given by the conqueror to William Peverill.

**DERBY**, the titular name of a distinguished family of the British aristocracy, descended from a common family with the barons Audley or Audleigh, co. Stafford. William de Audleigh, on exchanging with his cousin, sir Adam de Audleigh, the manor of Talk, co. Stafford, for that of Stanleigh (Stony Lea), co. Derby, adopted the latter name, and continued it to all his descendants. This event occurred in the 12th century. The first who assumed the arms now used by the family—viz., “three stags’ heads on a bend”—was sir William de Stanley, son of William de Stanley, who flourished in the reign of Henry III. The first Lord Stanley was created in 1456; his eldest son Thomas was created first earl of D. in 1485.

**DERBY**, EDWARD GEOFFREY SMITH-STANLEY, 14th Earl of, was b. 1799, at Knowsley park, Lancashire. He was educated at Eton and Christ-church, where, in 1819, he gained the Latin verse prize (subject, *Syracuse*). He was elected member of parliament for Stockbridge in 1820; in 1825, he married the second daughter of the first lord Skelmersdale; and in 1826, he represented Preston, but lost his seat in 1830, on becoming chief secretary for Ireland under the administration of earl Grey. A seat was then found for him at Windsor. He took a distinguished part in the debates in favor of the reform bill, and signalized his Irish administration by two bold measures—one for national education in Ireland, and another relative to the Irish church temporalities, which resulted in ten Irish bishoprics being abolished. The grievance of church-rates and first-fruits was also removed, and a graduated tax upon benefices and bishoprics substituted. In 1833, he became secretary of state for the colonies, and in the same year carried the bill for emancipating slaves in the West Indies, and providing a compensation of twenty millions to the planters. In 1834, being alarmed by the success of Mr. Ward's motion for appropriating the surplus of the Irish church temporalities to secular purposes, lord Stanley seceded from the Grey ministry, carrying with him sir James Graham, the duke of Richmond, and the earl of Ripon. He ever afterwards adhered to the conservative party, although, in 1834, upon the dismissal of the Melbourne ministry by William IV., he declined to join the administration of sir Robert Peel. After acting in concert with the opposition for seven years, he accepted the colonial seals in the Peel administration of 1841, and held them for four years. In Sept., 1844, he resigned his seat for north Lancashire, for which he had sat since 1832, and was called to the upper house in his father's barony of Stanley of Bickerstaffe. In Dec., 1845, when sir Robert Peel determined to repeal the corn laws, he retired from the cabinet. In 1846, he put himself at the head of the protectionist opposition, which, headed in the commons by lord George Bentinck and Mr. Disraeli, waged a stout but ineffectual opposition to the free-trade measures of sir Robert Peel. He was now regarded as the leader of the great conservative party. In 1851, on the death of his father, he succeeded to the earldom. In Feb., 1852, on the resignation of lord John Russell, he was sent for by the queen, and intrusted with the formation of an administration, which was, however, displaced in Dec. following by a hostile vote of the house of commons condemnatory of the budget of his chancellor of the exchequer, Mr. Disraeli. On the death of the duke of Wellington in 1852, he was selected to the post of chancellor of the university of Oxford. In Feb., 1858, when the Palmerston gov-

ernment resigned on the rejection of the conspiracy bill, he again became first lord of the treasury. At the meeting of parliament in the following year, his government brought forward a measure of parliamentary reform. A hostile amendment having been moved by lord John Russell, and carried, he dissolved parliament, and appealed to the country. When the new house of commons reassembled in June, 1859, a vote of want of confidence was carried against his government, and he resigned. He returned to power in 1866, and, in conjunction with Mr. Disraeli, passed the reform measure of 1867. See REFORM. In 1868, he resigned the premiership in favor of Mr. Disraeli. His last speech in parliament was made (1869) in opposition to the disestablishment of the Irish church. He died Oct. 23, 1869, and was succeeded in the earldom by his son, Edward Henry Smith-Stanley (see STANLEY). As a debater, the late earl stood in the very first rank. His power of invective was almost unequalled, and his vehement contentions with O'Connell on the repeal of the union and the Irish church did much to diminish the influence of the Irish agitator. He was tall, of commanding gesture, and his voice, in elevated passages of declamation, rang with power and effect. D. devoted the leisure of his latter years to translating Homer's *Iliad*, which was published in two volumes in 1864, in blank verse.

**DERBY DAY** is the second day, the Wednesday, of the grand spring meeting, which takes place at Epsom in Surrey, in May, in the week succeeding Trinity Sunday. Upon this day, the most important on the list, and that on which the best horses run, the famous Derby stakes, instituted by the earl of Derby in 1780, and which consist of 50 sovereigns each, are contended for. When the first Derby was run for, there were only 36 subscribers at 50 guineas each (with £25 forfeit in case of non-starters); but the number of subscribers is now so large, that the value of the stakes sometimes amounts to more than £6,000. The Derby Day is the great English holiday. To be present at Epsom on that occasion, London empties itself, and proceeds to the Downs by modes of locomotion the most heterogeneous. For hours, a continuous stream of carriages, gigs, dog-carts, vans, and vehicles of every description, moves tumultuously along the road to Epsom. Shopkeepers on that day shut up their shops, the benches of parliament are deserted, one half of the aristocracy appear on the ground, people of every condition arrive in countless numbers from all districts; and huge trains arrive every few minutes at the station, bringing their thousands, until the entire Downs are covered with a vast moving mass. So great is the demand for conveyances on this day, that scarcely a horse can be had either in London or within 40 m. of it. At the Derby in 1861, the course, which is a mile and a half in length, was gone over in 2 minutes 43 seconds—the swiftest running, by 2 seconds, ever yet known on that course.

**DERBYITES.** See PLYMOUTH BRETHREN.

**DERBYSHIRE**, an inland co. of England, lying between Yorkshire on the n. and Leicestershire on the south. Its shape is triangular; the greatest length from n. to s. being 56 m.; greatest breadth, 34; area, 1030 sq. miles. The north-west is occupied by the s. end of the Pennine chain, called the High peak or Derbyshire highlands. This tract forms the water-shed between the Trent and Mersey, and is not surpassed for rugged and romantic scenery by anything in England; abounding in precipices, faults, rocking-stones, caverns—one of which is 2,700 ft. long—and streams that often lose themselves for a time among the fissures of the limestone hills. The peak, the loftiest hill in D., is 2,000 ft. high. From the peak tract, a range runs s.; another runs 60 m. s.s.e. Other ranges intersect parts of the co. To the s., D. sinks into a flat or gently undulating tract of new red sandstone, with some spots of magnesian limestone and coal, and beds of red marl and gypsum. The chief rivers are the Trent—dividing D. from Staffordshire for 10 m., and then crossing the s. of the co. and passing into Nottingham—and its tributaries, the Derwent and the Dove, both of which rise in the region of the peak, and flow in a south-easterly direction. Warm mineral springs exist at Buxton and Matlock, and intermitting springs at Barmoor and Tideswell. D. is celebrated for metals and minerals—iron, lead, zinc, manganese, copper, coal, fuller's-earth, mineral caoutchouc and mineral oil, gypsum, pipe-clay and chert for potteries, marble, fluor-spar, and alabaster for ornaments, etc. D. has six canals, and is intersected by many branches of the Midland railway. In the n., the climate is cool and moist, with fogs, and often frosts in summer. D. is more a manufacturing and mining than an agricultural county. The best soils in the s. are red, marly, fertile loams. There are many woods and coppices. The chief crops are wheat, barley, and oats. The total acreage under crops of all kinds, bare fallow, and grass was 502,791 in 1876. D. has much permanent pasture, large dairies, and sheep-pasturage in the peak district. There are manufactures of cotton, silk, worsted, metallic goods, porcelain, and marble and spar ornaments. D. is divided into six hundreds, nine poor-law unions, and 140 parishes in the diocese of Lichfield. The chief towns are Derby, Ashbourne, Bakewell, Buxton, Chapel-le-Frith, Chesterfield, Belper, and Wirksworth. In 1871, the pop. was 379,394. D. returns eight members to parliament—six for the co., and two for Derby. There are in the co. remains of so-called Druid circles, barrows, cromlechs, British and Roman roads, Roman baths, and a Roman altar at Haddon hall. There are also ecclesiastical and monastic remains. Repton church crypt is older than 874. Hardwick hall contains some furniture of Elizabeth's time, and some embroidery said to have been done by

Mary queen of Scots. Near Bakewell is Chatsworth, the magnificent seat of the duke of Devonshire. Arkwright built his first mill at Cromford, in 1771. Brindley was born at Turnstead; and Strutt, the inventor of ribbed stockings, at Normanton.

**DERBYSHIRE SPAR** is a name given to the fluoride of calcium, or fluor-spar (q. v.)

**DERECKÉ**, a t. of Hungary, 12 m. s. of Drebrezczin. It is situated in the vicinity of several small lakes, from which, in the summer time, a considerable quantity of soda is obtained by evaporation. In one of the lakes, small but very beautiful pearls are found. Pop. '69, 7,334.

**DEREHAM**, EAST, a t. in the middle of the co. of Norfolk, 16 m. w.n.w. of Norwich. Its streets are wide, well lighted, and well paved. The church, which is cruciform, with a tower, contains the remains and monument of Cowper the poet. D. has manufactures of agricultural machines, and in the highly cultivated country around, there are many gardens and orchards. Pop. '71, 3,689. Here Withburga, daughter of king Anna, founded a nunnery in the 7th c., which was burned by the Danes, and afterwards refounded. Withburga was buried in her nunnery in 654, but her remains were stolen thence by the monks of Ely in 974.

**DERELICT**, a term in English law, signifying anything forsaken or left, or willfully cast away. Derelict lands, if suddenly left by the sea, belong to the crown; but if the sea has receded gradually and imperceptibly, the gain will go to the owner of the adjacent lands.

In order to constitute a ship which has been wrecked derelict, it is necessary that the master and crew shall have abandoned her, without hope of recovery. The mere quitting of a ship for the purpose of procuring assistance from the shore, or other temporary cause, with the intention of returning to her again, is not an abandonment. See Lord Stowell's judgment in the case of the *Aquila* (1 Rob. 37), and *Abbot on Shipping*, p. 489. When such abandonment or dereliction has occurred, the first-comers are entitled to take temporary possession of the ship, and to claim salvage, either from the owners, the lord of the manor, or other person having right to wrecks unclaimed by the owners, or in the event of no claim from the crown. The general superintendence of all matters relating to wreck is placed in the board of trade by the 439th section of 17 and 18 Vict. c. 104, commonly called "the Merchant Shipping act;" and the board may, with the consent of the commissioners of her majesty's treasury, appoint any officer of customs, or of the coast-guard, or other person, to be a receiver of wreck in any district, and to perform the duties imposed on him by the act. These duties consist in taking the command of the persons present, and availing himself of their services to the best of his ability to save the ship and her crew and cargo. If any one refuses to obey him, he shall incur a penalty of £50; and if any master of a ship or boat shall refuse him his aid, or any proprietor of a wagon, cart, or horses shall refuse him the use of them, he shall incur a penalty of £100. All articles washed on shore or lost are to be delivered to the receiver, and he has power to suppress plunder and disorder by force. Within 48 hours after taking possession of any wreck, the receiver shall cause to be posted up in the nearest custom-house a description of the same, and of any marks by which it is distinguished; and if the value of such wreck exceeds £20, he shall transmit a similar description to the secretary of the committee of Lloyd's (s. 452). See **LLOYD'S**. Goods deemed perishable he may sell immediately (s. 453). The owner of all wreck is entitled, within one year, to claim it from the receiver, who will deliver it up to him on receiving payment of such expenses, fees, and salvage as may have been incurred in terms of the act (s. 470). In the event of no owner establishing his claim before the expiration of a year from the date at which the wreck has come into the possession of the receiver, it shall be delivered up to the lord of the manor or other person having title to it. If a dispute arise as to the property of wreck, or the amount of salvage or other charge due, it may be decided by two justices, whose proceedings may be reviewed by any court of law or equity, if carried there by appeal within three months. If no claim shall be established to wreck either by an owner or lord of the manor, or admiral, mayor, or other person having title to wrecks cast on shore at particular parts of the coast, the wreck becomes the property of the crown, and shall be sold by the receiver, and the proceeds, after deducting fees and expenses, paid into her Majesty's exchequer (s. 475).

The principle upon which Salvage (q. v.) is given on wrecks and derelict is, that a person who by his labor preserves goods which the owner or those intrusted with the care of them have either abandoned in distress at sea, or are unable to protect and secure, is entitled to retain the possession of the goods until proper compensation is made to him for his trouble. Where the parties cannot agree on this sum, and are unwilling to adopt the decision of the justices, as above stated, the amount is generally ascertained by a jury. Till the question is decided, the goods remain in the custody of the salvor, or of the receiver for his behoof. No claim for salvage is due where the owner, or those in his employment, are at hand on the coast, and in a condition to save and protect his property. If any one set of persons have taken possession of a derelict, and are endeavoring to bring it into port and save it, another set have no right to interfere with them and become participators in the salvage; unless it appears that the first in possession would not have been able to effect the rescue of the property without the aid of the others (*Abbot*, p. 490). This rule applies to king's officers, even where the property

saved is government stores. The original salvors cannot be dispossessed without reasonable cause. As to the proportion which the salvage allowed bears to the value of the property saved in various circumstances see SALVAGE.

**DERG**, LOUGH (signifying the *red lake*), the name of two Irish lakes. One, the largest lake expansion of the river Shannon, between Tipperary on the s.e., and Galway and Clare on the n.w., is 24 m. long from n.e. to s.w., 2 to 6 broad, 10 to 20 ft. deep at the upper, and 50 to 80 at the lower end. Its surface is about 100 ft. above the sea. It contains several islands.—The other Lough Derg is in the s. of Donegal county, on the borders of Tyrone. It is 3 m. by 2½, has many small isles and rocks, and wild dreary shores, and is surrounded by mica-slate hills 700 to 1200 ft. high. Saint's Isle contains the remains of a priory, founded about 600, and is the original seat of St. Patrick's purgatory. But the place of penance has for some centuries been on Station Isle—under an acre in extent, and with two chapels—which is now the most celebrated place of pilgrimage in Ireland, 10,000 to 15,000 persons flocking to it annually, from 1st June to 15th August, for prayer, fasting, and vigils.

**DERIVATION.** See ETYMOLOGY

**DERIVATION**, in Medicine, a method of curing disease, by which it was formerly supposed that the *materies morbi*, or matter of the disease, was drained away through some channel established for it by artificial means, as when a blister is applied over an inflamed lung, or a discharge from the bowels established in a case of dropsy. Without too closely scrutinizing the theory, it may be admitted that many of the practices founded on it have also a pretty firm basis of experience, and are well established in modern medicine.

**DERMATOLOGY** (Gr. *dermatos*, of the skin, *logos*, a discourse), the science of the management of the skin and of its diseases. See SKIN.

**DERMATOPHYTES** (Gr. *derma*, the skin, and *phyton*, a growth or plant), vegetable growths, chiefly of the lowest of Cryptogamia (q. v.), inhabiting the cuticle or epidermis, and giving rise to some forms of skin-disease, as Favus (q. v.), Pityriasis (q. v.), Ring-worm (q. v.), etc.

**DERMESTES**, a genus of coleopterous insects of the section *pentamera*, and of the family *clavicornes* (q. v.); having antennæ shorter than the thorax, their three terminal joints forming an ovate compressed club. Their larvæ feed mostly on dry and decaying animal matter, and are very voracious, committing great ravages among furs, collections of natural history, etc. *D. lardarius* is the well-known BACON BEETLE, the larva of which is so often destructive to bacon and other dried meats, and often also to cheese. The perfect insect is about a quarter of an inch in length, and of a dull black color, the base of each wing-cover ash-colored with three black spots. The larva is of a long shape, tapering towards the tail, dark-brown above, white beneath, with long hairs, and furnished with two horny hooks on the last segment. The larva of *D. murinus* is common in the dried carcasses of vermin nailed up on doors by gamekeepers; that of *D. vulpinus* abounds among cargoes of hides brought from warm climates; that of *D. paniceus* in long-kept stores of ship-biscuits.

Use is sometimes made of the larvæ of species of *D.* for procuring well-cleaned skeletons of birds and other small animals: the animal is first soaked in water, to get all the blood out; then dried, to suit it to the taste of the larvæ, which are placed with it in a covered box; and in a short time their work is very neatly and completely done, much better than by ants.

**DERMIS.** See SKIN.

**DERMOPTEROUS** (Gr. skin-finned) **FISHES**, an order of fishes in Owen's classification, so named from the cutaneous vertical fins, in which the rays are extremely soft and delicate, or altogether imperceptible, and further characterized by the want of pectoral and ventral fins. Lampreys, the lancelet, etc., are dermopterous fishes.

**DERMO-SKELETON**, a term applied to the coriaceous, crustaceous, or osseous integument that covers most invertebrate and some vertebrate animals. It serves as a protection for the soft parts of the body.

**DERNA**, or **DERNAH**, a t. of Tripoli, northern Africa, situated at the mouth of a ravine a mile from the Mediterranean, in about lat. 33° 30' n., long. 22° 30' east. Built on both sides of the ravine, it has regular streets, which are far from cleanly, although a copious stream of pure water flows through several of them. The houses are low, and have a mean appearance, but they are surrounded by fine gardens and orange-groves. The harbor of *D.* is insecure, and its prosperity, which was formerly considerable, has now greatly declined. Pop. 6,000.

**DERREY EH**, EL, or **DERAY'EH**, a t. of Nedjed, central Arabia, in lat. 25° 15' n., long. 46° 30' east. It is fortified, and has a population usually stated at about 15,000. It was formerly the capital of the country of the Wahabees, but was captured and almost destroyed by Ibrahim pasha in 1819.

**DERRICK**, a mechanical contrivance used for the same purposes as the crane, but recently so improved in size, strength, and mechanism, as to be able not only to raise a body of 1000 tons in weight, but to transport it from one place to another. The fol

lowing description of the *Great Floating Derrick*, built in 1859, will convey an idea of the powers of this machine, and of the principles upon which it works. This derrick was built by the Thames iron ship-building company, at Blackwall. It consists of a flat-bottomed vessel, 270 ft. long, and 90 ft. across the beam, and is divided throughout into a number of water-tight compartments, which can be filled, so as to counterbalance any weight on an opposite side. From the deck of this floating steam-crane rises an iron tripod 80 ft. high, on the top of which revolves a gigantic boom, 120 ft. long, and above the boom the "king-post," a continuation of the tripod, rises to the height of 50 feet. One arm of the boom is furnished with ten fourfold blocks; the chains attached to these blocks are passed across the king-post, brought over the other arm of the boom, and so descend to the other side of the vessel, where they are connected with two powerful steam-engines, by means of which the weights are raised. This derrick is capable of being propelled by means of a series of bucket-paddle floats at the rate of 4 miles an hour. It is the invention of Mr. Bishop, an American. Derricks have been long in use in America, and have proved much more expeditious and economical than any other species of lifting-power. They are chiefly used for lifting machinery or other great weights, and for raising wrecks.

DERRY. See LONDONDERRY, *ante*.

**DERVISH** is a Persian word signifying *poor*, corresponding to the Arabic *Fakir* (q.v.). It designates, in Mohammedan countries, a class of persons resembling in many respects the monks of Christendom. The dervishes are divided into many different brotherhoods and orders. They live mostly in well-endowed convents, called Tekkiye or Changah, and are under a chief with the title of a Sheik, i.e., "elder." Some of the monks are married, and allowed to live out of the monastery, but must sleep there some nights weekly. Their devotional exercises consist in meetings for worship, prayers, religious dances, and mortifications. As the convent does not provide them with clothing, they are obliged to work more or less.

It is difficult to say when these religious orders took their rise. From the earliest times, pious persons in the east have held it to be meritorious to renounce earthly joys, to free themselves from the trammels of domestic and social life, and to devote their thoughts in poverty and retirement to the contemplation of God. In this sense, poverty is recommended by Mohammed in the Koran. Tradition refers the origin of these orders to the earliest times of Islam, making the caliphs Abubekr and Ali found such brotherhoods; but it is more probable that they arose later. Many Mohammedan princes and Turkish sultans have held dervishes in high respect, and bestowed rich endowments on their establishments; and they are still in high veneration with the people. The orders are generally named after their founders, and the best known are the *Bestamis*, established 874 A.D.; *Kodris*, 1165; *Rufaji*, 1182; *Mevelevis*, 1273; *Nakshibendis*, 1319; *Bektashis*, 1357; *Rushenis*, 1533; *Shemsis*, 1601; and *Jemalis*, 1750.

**DERWENT**, one of the principal rivers of Tasmania, issues from lake St. Clare, in the center of the island; flows tortuously towards the s.e.; waters Hobart-Town, the capital; and enters Storm bay, in D'Entrecasteaux channel, by an estuary of 4 m. in width. Up to Hobart-Town, the D. is navigable for ships of any burden. The lat. and long. of the mouth are about 42° 53' s., and 147° 25' east.

**DERWENTWATER**, or KESWICK LAKE, an oval sheet of water in the s. of Cumberland, and one of the most beautiful of the lakes of that county. It stretches s. from Keswick, is 3 m. long by 1½ broad, 72 ft. deep, and 222 ft. above the sea. Its banks are rocky and abrupt, and behind them rise rocky mountains, one of which, the Cat Bells, is 1448 ft. high, and another, Lowdore, has a fall of 100 feet. This lake is an enlargement of the Derwent river, which runs through the lake in its course towards the Irish sea, into which it flows at Workington. It has several wooded isles, besides a remarkable floating isle—a mass of earthy matter 6 ft. thick, and varying in size in different years from an acre to a few perches, covered with vegetation, and full of air-bubbles, which buoy it on the surface of the water. D. abounds in trout, pike, perch, and eels.

**DERWENTWATER**, JAMES, Earl of, one of the leaders in the rebellion of 1715, and the last earl of D., was the descendant of an ancient Northumberland family named Radcliffe. He was b. in 1688, educated in France, and on the death of his father in 1705, D., then in his 17th year, returned to the seat of his ancestors at Dilston, in Northumberland, and assumed the paternal titles and estates. On the eve of the insurrection, at the close of 1714, warrants were issued on suspicion against several gentlemen in the n. of England, and one, among others, against the earl of D.; but having been previously warned, he fled from Dilston, and found refuge in the cottage of one of his dependents. He soon afterwards collected a few retainers, and placed himself at their head, under the impression that the entire body of the Jacobites either had risen or were about to rise. From this period the history of the earl of D. becomes the history of the rebellion of 1715, which ended in the disastrous encounter at Preston, on which occasion D. conducted himself with the utmost heroism, but, with the most of the rebel leaders, was taken prisoner, and conveyed to the tower of London. Having been impeached of high treason at the opening of parliament, he was carried before the house of lords, Feb. 9, 1716, and, requesting time to prepare an answer to his accusation, was

remitted till the 19th, when, being taken for trial to Westminster hall, he pleaded guilty, and threw himself upon the mercy of the king. His appeal was unavailing, and he was condemned to suffer. Every possible effort was made by the relations and friends of D. to obtain a pardon, but their exertions were fruitless, and he was beheaded on Tower hill, 24th Feb., 1716. His youth, his invariable amiability of temper, his rank, and his bravery, combined to excite great sympathy for the unhappy sufferer.

**DERZA WIN**, GABRIEL ROMANOWICZ, a celebrated Russian lyric poet, was b. at Kasan, 3d July, 1743, studied at the gymnasium of his native city, and in 1762 entered the army as a private soldier. His talents and superior education soon procured him promotion. The empress Catharine highly esteemed him; and in 1791, appointed him secretary of state; in 1800, imperial treasurer; and in 1802, minister of justice. This last office, however, he held for only one year, when he retired on a pension, and devoted the remainder of his life wholly to the muses. He died 6th July, 1816. D. is a thoroughly original poet. He excels in loftiness of idea, purity of sentiment, and rich vigor of language; in fact, the latter quality at times manifests itself in an oriental extravagance of imagery which the colder fancy of the west fails to appreciate. D.'s noblest as well as his most popular ode is his *Address to the Deity*. It has been translated into English, German, and other European languages. His collected works were first published at St. Petersburg in 5 vols. (1810-1815), and have been often reprinted since.

**DESAGUADERO**, the name of various waters in Spanish America, of which the chief are a lake and two rivers.—1. The lake, situated in Araucania (q.v.), measures 25 m. in length, with an average breadth of 5, and sends forth the Osorno to the Pacific.—2. A river of the Argentine confederation, separates the departments of San Luis and Mendoza. It is, however, merely a winter torrent, being quite dried up in summer.—3. A river of Bolivia—the only stream of any magnitude that is wholly within its borders—issues from lake Titicaca, and, after a s. course of 190 m., loses itself in the land-locked lake of Aullagas, near the town of Oruro. It is, without exception, the loftiest stream of any length on either continent, for the elevation of its source, not greatly exceeding that of its mouth, is 12,846 ft., or nearly 2½ miles.

**DESAGUADERO**, a great plain between the e. and w. branches of the Bolivian Andes, two thirds of it in Bolivia and one third in Peru, about 400 m. long by 30 to 80 m. wide. This plain is 13,500 ft. above the sea. The region is rich in silver, copper, and tin, and there are probably other minerals. Thermal springs are a feature also. There are but two seasons, dry and wet, answering to summer and winter. Not a tree is to be seen. The lower valleys are covered with luxuriant grass, and afford excellent pasturage. Grain is not cultivated. Potatoes grow wild. The Indians make huts, boats, mats, and other articles of convenience, from native rushes. Cattle, horses, asses, and mules are plentiful. The most important animals are the guanaco, and the allied genera of alpacas, llamas, and vicuñas, all yielding valuable wool. Oruro is the most important town.

**DESAIX DE VEYGOUX**, LOUIS CHARLES ANTOINE, a general of the first French republic, was born at St. Hilaire-d'Ayat, in Auvergne, Aug. 17, 1768. After studying at the military school of Effiat, he was appointed in 1792 aid-de-camp to prince Victor de Broglie, then at the head of the army of the Rhine. Here D. distinguished himself by his bravery, which was at the same time cool and fearless. In 1796, Moreau, having obtained the command of the army of the Rhine, made D. his lieutenant, and employed him in the most difficult and dangerous missions. In Moreau's (q.v.) famous retreat through the Black Forest during this year, D., who commanded the left wing of the army of the Rhine, increased his already great reputation. The French by this retreat had now retired within the Rhine, retaining on the right bank only the fort of Kehl, which D. was commissioned to defend. The fort was in ruins, and could not be well repaired before the approach of the Austrians; nevertheless, behind this imperfect defense D. resisted the Austrian army for more than two months, only capitulating in Jan., 1797, when his ammunition was spent. His greatest achievement, however, was the conquest of Upper Egypt, which he accomplished in 1799, after an eight months' campaign. He was incredibly fertile in resources, and possessed the power of winning and restraining the people whom he had conquered to a wonderful degree; his own soldiers used to compare him to Bayard, while the inhabitants named him *The Just Sultan*. D. returned from Egypt just in time to take part in the battle of Marengo, on the 14th June, 1800, in which he was killed by a musket-bullet. His body was placed—after being embalmed—in the convent of Mt. St. Bernard. A statue has been raised in his honor in the Place Dauphine, in Paris.

**DE SANCTIS**, LUIGI, 1808-69; an instigator of the Protestant movement in Italy, for several years a Roman Catholic professor of theology. In 1847, he established a Protestant journal, the *Eco del Verità*; in 1868, he accepted the professorship of theology in the Waldensian seminary at Florence.

**DÉSAUGIERS**, MARC ANTOINE MADELEINE, 1772-1827; a French dramatist and composer of songs; author of many dramas, including comedies, operas, and vaudevilles, produced in rapid succession. His singing of his own songs made his company

greatly sought after. Late in life he undertook theatrical management, but with no great success.

**DESAULT, PIERRE JOSEPH, 1774-95;** a French anatomist and surgeon, who, when but 20 years of age, opened a school in Paris, where his success excited the wonder and jealousy of the established professors. In 1776, he was admitted a member of the incorporation of surgeons, and successively held other positions of honor. In 1782, he was appointed surgeon-major to the *De la Charité* hospital, and came to be regarded as one of the first surgeons of the age. He next went to the *hôtel Dieu*, and after Moreau's death the surgical department of the hospital was intrusted to him. There he instituted a clinical school for surgery, and attracted pupils from all countries, often having audiences of 600; and most of the surgeons of the period derived their knowledge in great part from his lectures. He introduced many improvements in the practice and in surgical instruments. During the revolution he suffered undeserved persecution, but was afterwards restored to favor.

**DES BARRES, JOSEPH FREDERICK WALLET, 1722-1824;** an English scientist; descendant of a Huguenot family which fled from France to England. He graduated from the royal military academy at Woolwich, and was sent to America as a lieutenant, where he was engaged in the French and Indian war. He was in the expedition against Louisburg, and in the siege of Quebec was aid to Wolfe, who fell into his arms when he received his death-wound. For some years afterwards Des Barres was charged with important engineering surveys in Nova Scotia, Newfoundland, and other British colonies, with a view of establishing a chain of military posts. He was also engaged in correcting old and making new charts of the North American coast, which were published in 1777, under the title of the *Atlantic Neptune*. In 1784, he became governor of the island of Cape Breton, and soon afterwards began to build the town of Sydney, where he opened the coal trade. In 1804, at the age of 82, he was made lieutenant-governor and commander-in-chief of Prince Edward's Island. He lived to be 102 years old.

**DESCANT, or DISCANT** (Sp. *discante*), a term which, in ancient times, was given to a musical composition; also to the counterpoint or melody which the singer (taking the upper part) sung extempore to the tenor or bass. In modern music, the term is applied to the part written for the voices of females or boys, and is the same as treble or soprano.

**DESCARTES, RENÉ** (Latinized into *RENATUS CARTESIUS*), the name of one of the reformers of philosophy, was b. Mar. 31, 1596, at La Haye, in Touraine. He was sent at the age of 8 years to the Jesuit college at La Flèche, where he soon became distinguished for his keenness of intellect, and made great and rapid progress in languages, mathematics, and astronomy. It was not long, however, before he became dissatisfied with the doctrines and method of scholasticism, and felt it impossible to acquiesce in what had hitherto been regarded as *knowledge*. The first thing that he did after leaving college, as we are informed in his treatise on method, was to abandon books, and endeavor to efface from his mind all that he had hitherto been taught, that it might be free to receive the impressions of truth, whencesoever they should come. In pursuance of his plan, he resolved to travel, and soon entered the army as a volunteer, serving successively in Holland and Bavaria. As, however, the life of a soldier contributed little to his main object, he quitted the army in 1621; and after making journeys in different directions, he at last retired to Holland, where he prepared most of his works, attracted many disciples, and at the same time became involved in several learned controversies, especially with the theologians. Although he loved independence, yet, in 1649, he accepted an invitation to go to Sweden, addressed to him by queen Christina, who desired his learned intercourse and instruction. His willingness to leave Holland was partly occasioned by his anxiety to escape from the hostility of his enemies. Only a few months after his arrival at the court of queen Christina, he died on Feb. 11, 1650. Sixteen years later, his body was brought to Paris, and buried in the church of St. Genevieve-du-Mont.

The grand object towards which D. directed his endeavors, was the attainment of a firm philosophical conviction. The way whereby he sought to attain this end, is explained in the discourse on method (*Discours de la Méthode*, published in 1637), to which we have already referred. This small, but extremely interesting and important treatise, contains a history of the inner life of the author, tracing the progress of his mental development from its commencement in early years, to the point where it resulted in his resolution to hold nothing for true until he had ascertained the grounds of certitude. The author also, in the same treatise, explains the practical rules whereby he resolved to be guided while in this state of *suspended belief*, and by the observance of which he hoped to arrive at *absolute certainty*, if, indeed, it were at all attainable. The results of his inquiries, so conducted, he exhibited more particularly in his *Méditations de Principiis Philosophiæ* (Amst. 1641), and the *Principia Philosophiæ* (Amst. 1644). In the former of these treatises, the independence of his thinking is strikingly brought out by his commencing his *Meditations* with the expression of doubt with regard to all that had hitherto borne the name of knowledge. After examining thoroughly, as he thought, the grounds of certitude in the various departments of knowledge, he found one, and only one, proposition that seemed to him to stand the test, and of which the truth could not possibly be doubted: that proposition was, that he existed, which he inferred from the fact of his possessing consciousness. He could not doubt that he felt and thought,

and therefore he could not doubt that *he*, the feeler, the thinker, existed. This relation between consciousness and existence he expressed by the memorable words: *Cogito, ergo sum*. Instead, however, of making the above proposition the foundation of his philosophy, by which he would have been led into a direction similar to that of Kant or Fichte, he employed it only so far as to ascertain from it the criterion of certitude—viz., that whatever is *clearly and distinctly thought, must be true*. Amongst these clear and distinct thoughts, he soon recognized the idea of God as the absolutely perfect being. This idea, he reasoned, could not be formed in our minds by ourselves, for the imperfect can never originate the perfect; it must be *connate*, i.e., part of the original structure of our understanding, and implanted there by the perfect being himself. Hence, from the existence of the idea of perfection, D. inferred the existence of God as the originator of it; he inferred it also from the mere *nature of the idea*, because the idea of perfection involves existence. But if God exist, then we have a guarantee of the previously determined ground of certitude, for God the perfect being cannot deceive, and therefore whatever our consciousness clearly testifies, may be implicitly believed.

The most general fundamental principle of the philosophical system of D., is the essential difference of spirit and matter—the thinking and the extended substances—a difference so great, according to D., that they can exert no influence upon each other. Hence, in order to account for the correspondence betwixt the material and spiritual phenomena, he was obliged to have recourse to a constant co operation (*concursus*) on the part of God; a doctrine which gave rise subsequently to the system called Occasionalism (q.v.), the principle of which was, that body and mind do not really affect each other, God being always the true cause of the apparent or occasional influence of one on the other. This doctrine received its complete development in the pre-established harmony of Leibnitz. See LEIBNITZ.

D. did not confine his attention to mental philosophy, but devoted himself systematically to the explanation of the properties of the bodies composing the material universe. In this department, his reforms amounted to a revolution, though many of his explanations of physical phenomena are purely *a priori*, and certainly sufficiently absurd. His corpuscular philosophy—in which he endeavored to explain all the appearances of the material world simply by the motion of the ultimate particles of bodies—was a great advance on the system held up to that time, according to which, special qualities and powers were assumed to account for every phenomenon. It was in mathematics, however, that D. achieved the greatest and most lasting results; and, indeed, his mathematical discoveries procured among his contemporaries, for him, in many cases, wild philosophical views, a greater importance than they in themselves are entitled to. It was D. who first recognized the true meaning of the negative roots of equations; and we owe to him the theorem, which is called by his name, that an equation may have as many positive roots as there are changes of sign in passing from term to term, and as many negative roots as there are continuations of sign, and not more of either kind. He gave a new and ingenious solution of equations of the fourth degree; and first introduced *exponents*, and thereby laid the foundation for calculating with *powers*. He showed, moreover, how to draw *tangents* and *normals* at every point of a geometrical curve, with the exception of mechanical or transcendental curves; and, what perhaps was his highest merit, he showed how to express the nature and the properties of every curve, by an equation between two variable co-ordinates; thus, in fact, originating *analytical geometry*, which has led to the brightest discoveries. D. was less happy in his cosmological exertations, in which he attempted to explain the movements of the heavenly bodies by *vortices* (*tourbillons*), consisting in the currents of the ether which he supposed to fill the universe; a theory which not only then, but even after the discoveries of Newton, made a great noise, and found many adherents, but which has long ago been consigned to oblivion. The philosophical and mathematical works of D., which are composed in Latin, were published at Amsterdam (9 vols. 4to, 1692–1701, also in 1713), and at Paris (1724–1726, in 13 vols. 12mo). More recently, an edition of his whole works has been published by M. Cousin (11 vols., Paris, 1824–26).

**DESCENDANTS.** See HEIR, CONSANGUINITY, etc.; SUCCESSION.

**DESCENT, LINE OF SWIFTEST,** is that by which a body falling under the action of gravity, passes most quickly from one point to another. It is proved that, when the one point is not directly over the other, the line of swiftest descent is an arc of a cycloid (q.v.).

**DESCHAMPS, EUSTACHE (MOREL),** a poet of France of the 14th century. His life was a long series of tournaments, feasts, and battles, and he was one of the most popular men of his time. He saw the English invasion of 1358; was at the siege of Rheims, and witnessed the march on Chartres. In 1360, he became the vassal of the young princess Isabella, to whom he paid all possible poetic homage. He was a great traveler, but in France he lived the true life of a *trouvère*, wandering from castle to castle with his poems. He was master of arms to Charles V., who appointed him governor of Fismis. One of his ballads is addressed to Chaucer, the English poet. None of his works were published until 1832.

**DESERET.** See UTAH.

**DESERT** (*desertus*, solitary), a term used to denote any portion of the earth's surface which, from its barrenness, as in the case of the arid places of northern Africa and Arabia, or from its rank exuberance, as in the case of the *sileas* of South America, is unfitted to be the site of great commercial and industrial communities. Many names, each differing in meaning to some extent, are employed to designate the desert-lands of different countries. The *desert* proper may be said to signify the vast sandy plains of Africa and Arabia; while the flats extending from the Black sea on the n., and from Persia on the s., onward across Thibet and Tartary to the north-eastern coasts of Asia, are called *steppes*; those in the northern division of South America, *sileas* or desert-forests; those in the other portions of South America, *llanos* and *pampas*; and those in North America, *prairies* or *savannahs*. All these, though widely differing in individual characteristics, have in common the important physical features of wide extent and uniform general level. The *oases*, which are occasional spots in the desert where springs arise, and where the waste is enlivened by the presence of vegetation, are usually lower than the general level of the surrounding plain. The great and famous desert-ground, however, is to be found in the old world. A huge tract of comparatively rainless country stretches almost continuously from the north Atlantic to the shores of the north Pacific, thus forming a great belt of sand from e. to w., along the whole extent of the eastern hemisphere. Beginning from cape Nun on the n.w. coast of Africa, the *Great Sahara*, the grand type of all desert-grounds, stretches away eastward from the shores of the Atlantic to the banks of the Nile, its eastern division being frequently called the desert of *Libya*. Crossing the Nile, by the irrigation and inundations of which alone Egypt is preserved from subsiding into the waste condition of the surrounding country, the desert is again found, interposing a strip of hot sand between the right bank of the Nile and the western border of the Red sea, upon whose shores no rain ever falls. On the right shore of the Red sea, desert-grounds unvisited by any rains prevail over the greater portion of Arabia, and stretch onward, with occasional interruption, over Persia, Thibet, and the Tartaries. The most extensive desert in the eastern portion of these arid districts is called the desert of Gobi, which extends from the western extremity of Thibet n.e. to the shores of lake Baikal. The cause of this extraordinary zone of parched land and of similar smaller tracts in other parts of the world, will be best explained under the head of **RAIN**.

**DESERTAS**, the general name of three rocky islands in the Atlantic ocean, situated to the s.e. of Madeira, in lat.  $32^{\circ} 31' \text{ n.}$ , long.  $16^{\circ} 30' \text{ west}$ . The southern and largest island is called Bugio; the center one, *Deserta Grande*; and the northern, *Chão*. *Deserta Grande* has a length of 6 m., with a breadth of from  $\frac{1}{2}$  a m. to 1 m.; *Chão* and Bugio are only about 1 m. in length—the latter about the same in breadth, but the former not more than a quarter. The D. are not inhabited, but they yield considerable pasturage, and are visited at certain seasons of the year by fishermen and herdsmen.

**DESERTER**, a soldier or seaman who forsakes his flag. In time of war such an act is punishable with death or otherwise as a court-martial may decide. In time of peace, the punishment is comparatively light.

**DESERTION** from the public service of the country is the crime of a man absconding, during the period for which he is enlisted, from the service of the army or navy. This crime was, by certain old statutes, made punishable with death; but now the punishment for desertion is prescribed by the annual mutiny acts. By these annual acts, any court-martial may inflict a sentence of corporal punishment, not exceeding fifty lashes, for desertion, and may in addition award imprisonment for the period prescribed by the articles of war. By 20 Vict. c. 13, s. 35, and 22 Vict. c. 4, s. 25, it is provided that deserters may be marked on the breast in gunpowder or ink with the letter D. This provision is omitted in the mutiny act, 1860. Recruits deserting before they have joined their regiments, are to be taken to the regiment nearest to the place where they were found, but to suffer no punishment except loss of bounty. Inducing to desert was formerly punishable by death; the punishment has, by modern statutes, been commuted to penal servitude. If simply "absent without leave," a British soldier, besides undergoing some kind of punishment, forfeits his regular pay for the days of absence; but if his non-appearance involves actual desertion, he loses all claim to additional pay, good-conduct money, and pension. The number of deserters from the British army is very great. In one particular period of 8 months, it was found that no less than 8,822 men deserted from the regular army, and 6,614 men from the militia; in 1874, 7,939 men deserted from the army, and in 1875, 5,629. Many experienced officers attribute the evil to the temptations of bounty, rather than to any other cause (see **BOUNTY**); and advise that the same amount of money should be applied to the soldier's benefit in some other form.

Desertion is equally a crime when committed by a seaman of the royal navy as by a soldier. A sailor absent from three successive musters is a "runaway," and when discovered and brought back, his punishment consists in a deduction of his wages. If his absence is continued, it amounts to desertion. All harboring of deserters by other persons is punishable. The year 1860 was marked by great and scandalous desertions from the royal navy; the cause is very obscurely known, but is generally referred to

some points of superiority in the merchant-service, which tempt the seamen away from their duty.

**DESERTION OF SPOUSE.** Before the passing of the divorce and matrimonial court acts, there existed in England no means whereby a wife, willfully deserted by her husband, could obtain redress. By 20 and 21 Vict. c. 85, and 21 and 22 Vict. c. 108, desertion by either spouse is made a ground of judicial separation, and desertion coupled with adultery is a ground for dissolution of marriage. The same acts make provision for the protection of property acquired by a wife who has been deserted. In such cases she can go before justices of the peace, who can make a protecting order. Since 1873, the divorce court is part of the high court of justice.

In Scotland, where the wife deserts the husband, she forfeits her claim to aliment; but in the event of her contracting debt for necessities, the husband will be liable in payment unless he show that the tradesman was aware of the separation. It is said that she may claim her legal provision of terce on the husband's death, though she have deserted him. A husband deserting his wife continues liable to aliment her; and she can now obtain a similar protection order to that allowed in England, which has the effect of securing her earnings against the husband should he return. This order, however, can only be obtained in Scotland from the lord ordinary, and with greater difficulty and expense than in England, 24 and 25 Vict. c. 86, Fraser *On Domestic Relations*, 458, 680. See DIVORCE; JUDICIAL SEPARATION.

**DESERTION OF THE DIET.** See DIET, DESERTION OF.

**DESFONTAINES, RENÉ LOUCHE,** 1751-1833; a French botanist. He began the study of medicine in Paris, took his degree in 1783, and was elected to the academy. He went the same year to N. Africa, and spent some time in scientific explorations in Barbary, returning with a large collection of plants and objects in natural history. He was then appointed professor in the famous Jardin des Plantes, and made that place thenceforth his world. He escaped the perils of the revolution, although on two occasions he ventured from his retirement to rescue the naturalists Ramond and Lheritier from prison and probably death. At the establishment of the legion of honor, Desfontaines was admitted one of the members. At the age of 63 he married a young wife, but she soon died. In 1831, he became blind and could thereafter recognize his favorite plants by touch alone. He was the author of an important work on the flora of the Atlantic coast, and of many valuable essays on his favorite subjects.

**DESFUL.** See DIZFUL, *ante*.

**DESHA,** a co. in s.e. Arkansas on the Mississippi, and intersected by White and Arkansas rivers; 600 sq.m.; pop. 70, 6,125—3,934 colored. It is low and subject to inundation; productions agricultural. Co. seat, Napoleon.

**DESHOULIERES, ANTOINETTE DU LIGIER DE LA GARDE,** 1634-94; a French poetess, daughter of the chevalier de la Garde, mistress of the palace to the queens Mary de Medici and Anne of Austria. She won the friendship and admiration of the most eminent literary men of the age, some of whom gave her the title of "the Tenth Muse." Her writings embrace almost every form of verse, and included a number of dramatic pieces. Voltaire pronounced her the most successful of the female poets of France.

**DESICCANTS**, in medicine, are substances with astringent properties, which are serviceable in checking secretion and exhalation.

**DESICCATION** is the process of drying by the employment of heat, dry air, or chemical agents which have an affinity for water. Examples of the class of *desiccants* or drying substances are fused chloride of calcium, quicklime, fused carbonate of potash, and oil of vitriol. The latter is employed by being placed in a separate vessel near the substance to be dried, and under a bell jar.

**DESIGN**, a preliminary work, either in outline or color, in which the conception of the artist is indicated, and more or less fully expressed. The design ought to exhibit the whole composition and drawing of the work, though the last only in a general way. The design ought thus to be a correct, though not a complete representation of the future work. When colors are employed in a design, it is rather tentatively, and for the purpose of ascertaining what their effect will be, than with a view to actually producing the effect required. A sketch differs from a design, inasmuch as the former is generally applied to a first drawing from an object placed before the artist; the latter, to a first drawing of an object which he has imagined, either wholly, or in the attitude and combinations in which he represents it. In architecture, the term is applied to a drawing mathematically correct, but in which the effects to the eye which will ultimately be produced by distance and by light and shade, are altogether ignored. An architectural design is consequently scarcely intelligible on first sight.

Designing on wood for wood-cuts or engravings is now a distinct profession, followed by a class of artists. A design of this kind consists of a drawing in pencil on the wood, the effects being as closely as possible what the printed engraving is intended to represent. See WOOD-ENGRAVING.

**DESIGN, GOVERNMENT SCHOOLS OF**, the original designation of what are now officially termed "schools of art." The establishment of schools of design had for its object the training of designers and artisans in the principles and practice of the fine arts, with a view to the improvement of the artistic quality of our manufactures, by imparting, where requisite, more symmetry of form, harmonious arrangement of coloring, and general appropriateness of decoration. To Scotland is due the credit of having taken the lead in this matter, schools having been established at Edinburgh in 1760, "for teaching and promoting the art of drawing for the use of manufacturers, especially the drawing of patterns for the linen and woollen manufactures." In 1837, a central school of design was established at Somerset house in London, followed shortly afterwards by about twenty branch schools in important seats of manufacturing industry. These schools were at first placed under the control of the board of trade, and the education in art afforded by them was in a great measure restricted to students of the artisan class. This attempt, however, to circumscribe the action of the schools, gradually gave way to the admission of a more mixed element into their rôle of students; but no radical change took place in the management of these schools until 1852. The great exhibition of 1851, which brought to light the marked deficiency in the artistic element of British as compared with foreign manufactures, was no doubt the main cause of the subject of national art education being taken up with renewed vigor. About this time Mr. Henry Cole was made general superintendent, and to him may in great measure be ascribed the complete reorganization of the government scheme for national art education that soon followed. It was grounded on the conviction that in order to improve the artistic taste of our manufactures, the first step was to elevate the art education of the people at large. For this end it was to be brought into closer alliance with the system of general education. A national art training-school for educating art-teachers was instituted at Marlborough house. The nucleus of an industrial museum was also formed there, the government granting a fund of £5,000 for the purchase of specimens of industrial art from the great exhibition collection. Such was the comparatively humble origin of its wealthy and magnificent successor, now established at South Kensington. From this date a rapid increase took place in the establishment of schools of art, which now number more than 120, situated all over the country; besides this, a comprehensive system of art-teaching is carried on in other educational institutions. The following is a summary of the official arrangements for promoting this work, abridged from the *Science and Art Directory*, 1875, of the committee of council on education, South Kensington:

*Establishment of a National Art Training-school.*—A central school, for the benefit of the United Kingdom, is established at South Kensington for the training of art masters and mistresses, and for the training of students in drawing, designing, and modeling, to be applied to the requirements of trade and manufactures. A limited number of students are received into training as art-teachers, receiving a maintenance allowance, which is proportionate to their attainments and the certificates of qualifications obtained by them; in return for which they may be required to perform certain duties as teachers, and must engage to accept the situations to which they are recommended.

*National Art Scholarships.*—A limited number of duly qualified students from the local schools of art, who may have given evidence of special aptitude for design, are eligible for appointments to national scholarships in the national art training-school, with weekly allowance for maintenance: these appointments are for one year only, but in cases of marked proficiency they may be renewed for a second year.

*Aid to Schools of Art, etc.*—The department will aid the instruction given in schools of art, when under the direction of a local committee of not less than five well-known responsible persons, and instructed by teachers holding one or more art certificates of the third grade, provided that day classes be held, and that artisan night classes are taught at least three times in each week for two hours. A system of payment on results of teaching is made, on account of persons of the industrial classes, teachers, or their children above twelve years of age, who pay fees for their instruction. In a similar way the department gives aid to the teaching of drawing in art night classes to artisans, in elementary day schools, and training colleges for teachers.

*Annual Examinations.*—At the close of April or beginning of May in each year, a competitive local examination in drawing is held in all the schools of art on two consecutive evenings, conducted by means of examination papers supplied by the department, the subjects given being free-hand and model drawing, practical geometry and linear perspective, certificates and prizes being awarded to the successful competitors. The works of the students from all the schools of art are annually transmitted to the department in April for inspection, prizes being awarded to the most meritorious.

*National Competition.*—The best of the more advanced of the above works are selected to compete with each other in this competition, which is annually held at Kensington in the month of May. The prize list for awards in this competition includes 10 gold, 30 silver, and 60 bronze medals. Additional prizes of works of art, books, etc., are also awarded.

*Prizes to Art Masters.*—Monetary prizes are awarded annually, to the head-masters of schools of art, for the most satisfactory results in teaching.

*Circulation of Books and Examples.*—The art library and collections of decorative

art, etc., at S. Kensington are as far as possible made available for the purposes of instruction of schools of art.

*Grants for New Buildings, and Purchase of Examples.*—In aid of new buildings to be adapted for schools of art, a grant not exceeding 2s. 6d. per superficial foot of internal area is made, up to a maximum of 4,000 feet. Grants of 75 per cent are made towards the cost of art examples selected from lists approved by the department, on behalf of art schools, mechanics' and other educational institutions."

**DESIGNS, COPYRIGHT IN.**—Designs for articles, whether of ornament or utility, are protected by various statutes. Of these, the most important are the act to consolidate and amend the laws relating to the copyright of designs for ornamenting articles of manufacture, of 1842 (5 and 6 Vict. c. 100), etc., to 24 and 25 Vict. c. 73. By the 21 and 22 Vict. c. 70, the protection which the former had granted for nine months, is extended to three years, to be computed from the time when the design was registered. By section 5, it is provided that the registration of any pattern or portion of an article of manufacture to which a design is applied, instead of, or in lieu of, a copy, drawing, print, specification, or description in writing, shall be sufficient. The copyright is only acquired where there was no previous publication except such as takes place at an exhibition (23 and 24 Vict. c. 27). The other statutes are 6 and 7 Vict. c. 65, 13 and 14 Vict. c. 104, 33 and 39 Vict. c. 93, and 24 and 25 Vict. c. 73. By the last-mentioned statute, the application of the design to articles of manufacture need not be done within the United Kingdom, as was the case under the first act, but the protection of the act applies generally, and whether the inventor or proprietor of the design be a British subject or not.

**DESIGN, SCHOOLS OF** (*ante*), institutions where the arts of ornamental and mechanical drawing are taught. They are numerous in the United States. One of the oldest is the "National Academy of Design," founded 1825, in New York, whose annual exhibitions of paintings (April to July) are well known. Another, entirely free to all students, is in the Cooper institute in the same city. In the public school system of Massachusetts free instruction in drawing is provided.

**DESIO**, a t. of n. Italy, province of Milan. It is a well-built town, surrounded with garçons and vineyards, and has a fine hospital. Pop. 5,500.

**DESIRA'DE**, or **DESIDERA'DE**, or **DESËA'DA**, the first of Columbus's discoveries during his second voyage, lies about 4 m. to the e. of Guadeloupe, of which, under France, it is a political dependency. It measures 6 m. by 2, and contains (1871) 1637 inhabitants, chiefly emancipated slaves. The surface is elevated in proportion to the area, and the soil, though not generally fertile, is yet said to yield excellent cotton.

**DESMAN.** See **MUSK RAT**.

**DESMIDIEÆ**, according to the prevalent opinion of naturalists, a tribe or group of *algæ*, and as such ranked by some botanists among *diatomacæ* (q.v.); whilst other naturalists regard them as belonging to the animal rather than to the vegetable kingdom, some also esteeming them to be vegetable who maintain the animal character of the true *diatomacæ*. They are amongst those lowest organisms which seem to connect the animal and vegetable kingdoms at their common starting-point. The *D.* are readily distinguished from the true *diatomacæ* by their rounded, not angular form, and by their want of silicious covering; also by their color, which is a herbaceous green, whilst the *diatomacæ* are generally brownish. Unlike the *diatomacæ*, they shrivel up, and lose their form in drying. They are, like them, microscopic, but are usually found in stagnant or very slowly running water, sometimes in brackish, but never in salt water. They may often be procured in great numbers, by pouring the water in which they exist upon a cloth; and if the cloth is kept moist, they will live for a long time, and their progress may be observed. They all exhibit a transverse constriction, sometimes not very distinct, but often almost dividing the single cell which forms the organism into two parts. It is at this constriction that new cells are formed; but this process ceases after a while, and a true reproduction takes place by spores, either through conjugation (q.v.) or swarming (q.v.). It is very much on account of these modes of reproduction, and of the presence of starch in the *D.*, that they are confidently referred by naturalists to the vegetable kingdom. Our knowledge of the *D.* has been much extended by the work of Mr. Ralfs on the *British Desmidiæ*.

**DES MOINES**, a co. in s.e. Iowa, on the Mississippi, drained by Flint river, and intersected by three railroads; 408 sq.m.: pop. '75, 35,106. It has a prairie and forest surface, with fertile and well cultivated soil. Agriculture is the chief occupation. Co. seat, Burlington.

**DES MOINES**, a city, the capital of Iowa, in Polk co., at the head of steam navigation on the Des Moines river, and the Chicago, Rock Island, and Pacific, and Des Moines Valley railroads; pop. '75, 16,130. The city is regularly laid out, on both sides of the river, on a plateau 15 or 20 ft. above the water. In the rear is much higher ground, on which are many fine residences. There are public buildings of importance, including the new state-house (estimated cost \$3,000,000); more than 20 churches, 3

national banks, 3 daily and 7 weekly papers, and extensive manufactories. It was chartered and became the capital of the state in 1855.

**DES MOINES RIVER**, the most important stream in Iowa, rising from a chain of lakes in Minnesota. It runs through about the center of the state and joins the Mississippi a little below the city of Keokuk. In its course of 300 m. it drains more than 10,000 sq. m. of fertile territory.

**DESMON CUS**, a genus of palms, with slender stems, climbing over shrubs and trees, like the rattans (*calamus*) of the East Indies. They are the only American palms of this character. They have alternate pinnate leaves, with long hooked spines, instead of several of the uppermost leaflets, which make them very formidable to those who attempt to penetrate the forests where they grow. The species are pretty numerous, and all American.

**DESMOULINS, CAMILLE**, one of the prominent personages of the French revolution, was b. in 1762 at Guise, in Picardy; studied law at the Collège Louis-le-Grand, Paris; but on account of a stutter in his speech, did not prosecute the profession. His mind was filled with lofty but confused notions of classical republicanism, which found vent on the eve of the revolution in his *La Philosophie au Peuple Français* (Par. 1788), and *La France Libre* (Par. 1789). To his exaggerated denunciation was owing that outburst of popular fury which resulted in the destruction of the Bastille on the night of the 14th July, 1789. In the events of the Champ de Mars, Aug. 10, 1792, D., like his friend Danton, took a leading part, but was less implicated in the Sept. massacres. Elected to the national convention by the people of Paris, he voted for the death of Louis XVI. His relation to Danton, which had always in it something of dependence, induced him to take up the pen against the Girondists, and in his *Histoire des Brissotins*, he covered these moderate republicans with ridicule. In this, however, D. was not quite sincere, for many of the Girondists he highly esteemed, and he was himself by nature much more like Vergniaud and Brissot than like Robespierre and St. Just. When the guillotine was erected, D. saw his error, and bitterly repented his facile folly. Towards the end of 1793, he began to publish *Le Vieux Cordelier*, a journal which recommended, among other things, that the forms of justice should be restored, and attacked the members of the *Comité de Salut Public*. Twice accused before the Jacobin club, he was at length, on the night of the 30th Mar., 1794, along with Danton, arrested, and brought before the revolutionary tribunal. When asked his age, D. replied: "J'ai l'âge du sans-culotte, Jésus, c'est-à-dire trente-trois ans, âge fatal aux révolutionnaires." He was condemned without a hearing, and mounted the scaffold along with Danton, April 5, 1794. His wife, the beautiful Lucile Duplessis, vainly endeavored to excite an insurrection in his favor, and a fortnight after, she also was executed.—D. was essentially an enthusiast and hero-worshiper, always leaning for support on some stronger spirit than his own. His first idol was Mirabeau, after whose death he devoted himself to Danton. His aspirations were noble, his sympathies magnanimous, but he had neither sufficient moral resolution to oppose the political excesses of the popular party, nor even, until the close of his career, sufficient insight to assure him of their injustice and folly. Gifted abundantly by nature, as the light-hearted Camille was, with wit, fancy, and feeling, one cannot help regretting that he did not live in less troublous times, when he might have given to the world, in the form of poesy or fiction, the treasures of his rich and sparkling genius.

**DESNA**, a river of Russia, rises in the government of Smolensk, 50 m. s.e. of the t. of that name. It flows s.e. through the governments of Smolensk and Orel, until it reaches Briansk, where it enters the government of Tchernigov, through which it flows s., then s.w. to the town of Tchernigov, and finally joins the Dnieper nearly opposite Kiev. The D. is 500 m. in length, and is navigable throughout almost the whole of its course. Its chief affluents are the Seim, from the left, and from the right, the Snov.

**DE SOTO**, a parish in n.w. Louisiana, on the Texas border, drained by Red and Sabine rivers; 910 sq. m.; pop. '70, 14,962—9,581 colored. Corn and cotton are the chief productions. Co. seat, Mansfield.

**DE SOTO**, a co. in n.w. Mississippi on the Tennessee border and the Mississippi, and crossed by the Mississippi and Tennessee railroads; 960 sq. m.; pop. '70, 32,021—17,745 colored. The surface is level and much of it swampy. Productions, wheat, corn, cotton, and butter. Co. seat, Hernando.

**DE SOTO, FERNANDO**, 1496—1542; one of the early Spanish explorers of North America. He distinguished himself when young in literary studies and athletic exercises. In 1519, he accompanied Pedrasias Davila, his patron, to the isthmus of Darien, and was a most daring and independent opponent of the tyrannical rule of that officer, who was afterwards governor of Darien. Leaving Davila's service, in 1528, he explored the coast of Guatemala and Yucatan, seeking for a supposed water communication between the Atlantic and Pacific. In 1532, he was in Pizarro's expedition for the conquest of Peru, and used all his influence with the Spanish butcher to prevent the murder of the Peruvian king. Having amassed a fortune, De Soto returned to Spain and married Davila's daughter. In 1536, moved by the reports of the mystical El Dorado, he undertook the conquest of Florida, and sailed in April, 1538, with 20 officers, 24 priests, and 600 men.

May 25, 1539, he landed at Tampa bay, and followed the track of Narvaez, a former Spanish invader. In July, 1539 his ships were sent back to Havana. In 1540, he slowly worked westward, having many conflicts with the Indians. His second winter was spent in the Chickasaw country. These Indians, in the spring, burnt his camp and their own villages, because he attempted to force them to carry his baggage, and 40 of his men were burnt to death. After several days of marching mainly through swamps he reached the Mississippi, June, 1541, being the first European to look upon that mighty river. He constructed rude barges and crossed over, marching towards the highlands of White river, the w. limit of his exploration. Turning s. and passing the hot springs of Arkansas, he passed his third winter on the Washita river. In the spring he moved down the Washita to the Mississippi; and was marching along the latter river when he was taken with fever and died either in May or June, 1542. To keep the knowledge of his death from the natives, his body was sunk at night in the middle of the river. His wife died at Havana on the third day after hearing of his fate.

**DESPOT AND DESPOTISM.** A despotism is a form of government which has for its object the interests either of an individual or of a class, to the exclusion of those of the whole community. In the former case, it is usually called a tyranny, which is the degenerate form of monarchy; in the latter, it may be either an oligarchy, which is the degenerate form of aristocracy, or an ochlocracy, which is the degenerate form of democracy. A despot is the individual or class in whose favor and for whose benefit such a government is carried on. A despot may thus include any number of persons, from unity upwards—from a monarch to a mob. Much of the confusion which attends political speculation, and many of the disasters which befall political life in modern times, would be obviated, if these terms were used in the strictly scientific sense which was assigned to them by the Greek politicians more than 2,000 years ago. See **MONARCH, TYRANT, DICTATOR.**

**DESSAIX, JOSEPH MARIE**, Count, 1764-1834: a gen. in the French service, who studied and began to practice medicine in Paris, but went to Savoy in 1791, where he formed a democratic association, and became a capt. of volunteers. He was actively engaged at the siege of Toulon, and served under Napoleon in Italy. He was one of the council of 500 of 1798, and opposed the *coup d'état* of the 18th Brumaire. He was made a brig.gen.; and, in the campaign against Austria, gen. of division. Napoleon gave him the title of "the intrepid," and the dignity of a count of the empire. He was appointed commander of the national guards at Lyons, after the revolution of 1830.

**DESSALINES, JACQUES**, some time emperor of the island of Hayti (St. Domingo), was imported into that island from the gold coast of Africa as a slave. On the liberation of the slaves, 4th Feb., 1794, he became one of the most prominent among the negroes who rose in insurrection against the white colonists. After the organization of the insurrection, D. occupied the position of 1st lieutenant to the leader Toussaint l'Ouverture; and in the wars against the French troops, was always distinguished by his agility and swiftness of movement, as well as by his fearlessness and ferocity. D. submitted, however, and took advantage of the amnesty granted on the capture of Toussaint in 1802; but shortly after, he headed another insurrection, attacked the French forces, defeated them in the battle of St. Mark, and compelled them to evacuate the island in Oct., 1803. He was created governor in Jan., 1804, when the people of the island declared themselves independent, and had himself crowned as emperor of Hayti, 8th Oct. of the same year, under the name of Jacques I.; but his despotism and cruelty soon alienated from him the sympathy and support even of those who were formerly his firmest adherents. On the 17th of Oct., 1806, D. was attacked and killed by Christophe, a negro chief, who succeeded him as emperor Henri I. of Hayti.

**DESSAU**, a t. of northern Germany, and capital of the duchy of Anhalt, is situated on the left bank of the Mulde, not far from its junction with the Elbe, about 80 m. by railway s.w. of Berlin. The country round the town is pleasant and is very industriously cultivated. D. consists of three parts, the old and new town, and the Sand, and it has besides three suburbs. It is, in general, well built, and one or two of the streets are particularly handsome. Among the principal buildings are the ducal palace, a noble structure, built in 1748, with a picture-gallery, and a library containing many MSS. of Luther; a town-hall, an elegant theater, and several churches and benevolent institutions. Its educational establishments are numerous and excellent. It has a fine cemetery, and the environs are surrounded by beautiful gardens. The manufactures are woolen cloth, hosiery, tobacco, and spirits. Pop. '75, 19,621.

**DE STAËL.** See STAËL-HOLSTEIN, *ante*.

**DESTERRO, NOSSA SENHORA DO DESTERRO**, or SANTA CATHARINA, a port of Brazil, the most important town in the province of Santa Catharina, on the w. coast of the island bearing the same name; 27° 30' s. and 48° 30' w.; pop. 8,000. It is strongly fortified; its harbor is excellent, and it has some foreign commerce. It is well laid out, but poorly built.

**DESTUTT DE TRACY, ANTOINE LOUIS CLAUDE**, Count de Tracy, 1754-1836; a French statesman, member of the provincial assembly of the Bourbonnais, and appointed delegate of the nobility to the states-general in 1789. He was a leader of reform meas-

ures. In 1792, he joined the army under Lafayette and followed him over the frontier. Returning secretly to France, he was arrested and imprisoned. After the revolution, he was made a senator. He voted for the overthrow of the empire in 1814, but opposed reactionary measures. He adopted the views of Condillac, and became an earnest materialist. He wrote, among other works, a *Commentary on the Spirit of the Laws*, which was translated by president Jackson for a text-book.

**DESUETUDE**, a technical term in the law of Scotland, signifying that repeal or revocation of a legal enactment which is effected, not by a subsequent enactment in a contrary sense, but by the establishment of a contrary use, sanctioned by the lapse of time and the consent of the community. The corresponding term in English law is *nonuser*; but neither the word nor the idea attached to it is familiar to that system. The rule in England is, that a statute once formally enacted by the legislature, remains in force, however unsuited it may be to the altered conditions of society, till it be repealed by another statute. The repeal may be by implication, but here the law watches with a jealous eye. Such repeal "is to be understood," says Blackstone, "only when the matter of the later statute is so clearly repugnant that it necessarily implies a negative. As, if a former act says that a juror upon such a trial shall have an estate of 20 pounds a year; and a new statute afterwards that he shall have 20 marks—here the latter statute virtually repeals the former." So far was this principle carried, that it was formerly the rule, that if a statute repealing another was itself repealed afterwards, the first statute was revived without any formal words for that purpose. But this rule has been changed by 13 and 14 Vict. c. 21, s. 5 and 6, which enact that where any act repealing, in whole or in part, any former act, is itself repealed, such last repeal shall not revive the act or provisions before repealed, unless words be added for that purpose; and that where any act shall be made, repealing in whole or in part any former act, and substituting provisions instead of those repealed, such repealed provisions shall remain in force till those substituted shall come into operation by force of the last made act. In Scotland, an opposite principle prevailed, and it is still held that acts of parliament made before the union may lose their force by disuse, without any express repeal, or "go into desuetude," as it is commonly said. But by D. is meant something more than mere non-use for a period of time, however great. There must be contrary use of a positive kind, inconsistent with the statute, and of such a kind as to prove the altered sense of the community; there must, in short, be consuetudinary law in a negative sense; and the so-called D. thus amounts to a repeal of statute law by consuetudinary law. Both rules are liable to objections. The result of that followed in England has been, that statutes have remained on the statute-book without formal repeal, after their enforcement had become morally impossible. Of this it may be mentioned, as one single example, that the judicial combat was formally demanded in virtue of an unrepealed statute, and had in point of form to be conceded in the present century. See DUEL. But, since 1869, the English statutes have been weeded of all obsolete and inconsistent enactments, and a new edition has been published by authority, containing only such parts as are in force. The rule in Scotland is entirely the same as the English as to all statutes made since the union; but as regards the older Scotch statutes, the difficulty still exists in dealing with enactments more or less forgotten or violated, and in determining what constitutes such contrary use as to support the plea of desuetude. The best arrangement is now adopted, whilst retaining the Scottish rule as correct in principle, to endeavor, by purging the statute-book of all obsolete enactments, to render its practical application as limited as possible.

**DETACHMENT**, in military matters, is a small but indefinite number of troops, sent for some special duties away from the regiment, brigade, division, or army, as the case may be. In a fleet, also, a D. of one or more ships may be told off in a similar way.

**DETERMINANTS**, the name given to a new method of great use, *inter alia*, in the solution of equations embracing several unknown quantities, whereby the student can almost on inspection write down the values, in terms of the known quantities, of each of the unknown.

**DETERMINATE PROBLEM**, in geometry, a problem of a limited number of solutions; as: "Given the base, perimeter, and area, to construct a triangle." For this there are four general solutions. But if either of the three propositions be omitted, it becomes indeterminate.

**DETINUE**, in English law, an action for the recovery of goods wrongfully detained, or their value, with damages and costs. The action is for the recovery of a specific article; the goods detained must, therefore, be of such a character that they can be distinguished from others, as a horse, money in a bag, etc. In this respect, the action of D. differs from an ordinary action at law, and judgment in D. is accompanied by its special remedy for enforcing execution—called writ of *distringas*. There must actually be a title of property in the plaintiff at the time he brings his action; but property without possession is sufficient, and an heir can thus bring his action for an heirloom which has never been in his possession. This action was formerly subject to *waager of law* (q. v.), now abolished, whereby the defendant was allowed to clear himself by his own oath, supported by that of eleven neighbors. This proceeding rendered the action of D. so

inconvenient, that, by a fiction of law, remedy for wrongful detention was most frequently sought by the action of *trover* (q.v.).

**DETMOLD**, a t. of north-western Germany, on the Werre, capital of the principality of Lippe-Detmold, 47 m. s.w. of Hanover, consists of an old and new town, the latter of which is well built, and adorned with public walks and gardens. The chief buildings are the palace, a fine old castellated edifice, the gymnasium, and the theater. D. has also a training-school, a public library, and a hospital. The manufactures are leather, woollens, and linens. There are also several breweries. On the Grotenburg, about 2 m. from D., is a colossal copper statue of Hermann (q.v.). Pop. '75, 6,982.

**DETONATION** is the phenomenon of combustion with explosive rapidity, accompanied by sound and light. Thus the firing of gunpowder, gun-cotton, and fulminating powders, as in a percussion-cap, is detonation.

**DETRITUS**, applied in geology to accumulations formed by the disintegration of rocks, which consist of gravel, sand, or clay, or of an admixture of them.

**DE TROBRIAND**, PHILIP REGIS, b. France, 1816; a man of letters, long resident of the United States. In the war of the rebellion he was an officer on the union side, and became brevet-brig.gen. in the United States army. He has written a number of works in French, including *Four Years in the Army of the Potomac*. From 1854 to 1861, he was editor of the *Courrier des Etats Unis*, the leading journal in the French language in the United States.

**DETROIT** (French for strait) is that part of the St. Lawrence which discharges into St. Clair into lake Erie. With a s.s.w. course, it forms the lowest section of that mighty body of waters before it assumes its n.e. direction towards the gulf of its own name. It is about 28 m. long, with a minimum breadth of fully half a mile. Though the middle of its length is barely above the 42d parallel—about 550 m. to the s. of any point in England—yet it is frost-bound for about four months in the year. It is navigable for vessels of any burden, the deeper channel being on the Canadian shore.

**DETROIT**, the chief city of Michigan, the oldest city by far in the w. of the United States, and older than either Baltimore or Philadelphia on the seaboard, was founded by the French of Canada in 1670, as an outpost for the prosecution of the fur trade, on the right bank of the river of its own name. For more than a century and a half, however, the advantages of its position were rather prospective than actual. The settlement of the adjacent wildernesses was so slowly carried into effect, that Michigan, of which D. was the capital, continued to be a subordinate territory, as distinguished from a sovereign state, from 1805 to 1837. Accordingly, as late as 1830, the place contained only 2,222 inhabitants. But in 1840, the pop. had risen to 9,102; in 1850, it was 21,019; and in 1870, 79,577. According to the official returns of the United States, the value of the imports in the year ending June 30, 1874, was \$1,450,072 (£290,014), and of the exports \$3,293,440 (£658,688). In 1875, the assessed value of real estate amounted to \$90,000,000, or £18,000,000. D. has 34 newspapers and periodicals, of which 8 are issued daily. Besides a net-work of navigable communications, which, with the aid of art, has added the open ocean and the gulf of Mexico to the St. Lawrence, D. is a center from which 8 railways radiate. Eight lines of street-railway, with 40 m. of track, intersect the city. Among the chief buildings are the city hall, 200 ft. long, and 180 ft. high to the top of the tower, completed in 1871, at a cost of \$600,000; the opera-house; and the custom-house. D. has a well-organized system of public schools, and possesses 64 churches, of which the largest is the Roman Catholic cathedral. It is supplied from the river with water, which is forced into a reservoir 50 ft. high. The manufactures are extensive and important, consisting of steam-engines, machinery, stoves, cabinet-ware, bricks, tobacco, etc. Brewing and tanning are also largely carried on.

**DETROIT** (*ante*), the most populous city of Michigan, and the capital of Wayne co., on the w. bank of the Detroit river, about 18 m. from lake Erie and 7 m. from lake St. Clair. The site is sufficiently elevated above the river to afford excellent facilities for drainage, which have been thoroughly improved. The river, which is the dividing line at this point between the United States and Canada, is half a mile wide and over 30 ft. deep, forming the best harbor on the lakes. The city extends 6 or 7 m. along the bank of the river and from 2 to 3 m. back from it. The river front is lined with warehouses, mills, foundries, grain elevators, railway stations, shipyards, dry docks, etc., the signs of an enterprising and thriving community. Fort Wayne, a mile below, commands the channel. The site of the city was visited by the French early in the 17th c., but no permanent settlement was made by them until 1701. Sixty-two years later, in 1763, at the close of the war between England and France, it fell into the possession of the English. Immediately after this, Pontiac, the great Ottawa chief, made a desperate but unsuccessful effort to expel the whites from all that region. In 1778, Detroit contained only 300 inhabitants, living for the most part in log huts. A Roman Catholic church had survived from the days of the French possession. The British, in 1778, erected a fort, which, after the Americans gained possession, became Fort Shelby. At the peace of 1783, Detroit became a part of the United States, but the Americans did not take possession until 13 years later. The place was wholly destroyed by fire in 1805, and two years afterwards the present city was laid out. In the war of 1812 it was surrendered

by gen. Hull to the British, but recovered by the Americans after the battle of lake Erie in 1813. It was incorporated as a village in 1815, as a city in 1824. It was the seat of government of the territory of Michigan from 1805 to 1837, and of the state of Michigan from the latter date till 1847. The plan of the city is not altogether harmonious, but the streets are broad and well paved and lighted, many of them lined with beautiful shade trees. The avenues are from 100 to 120 ft. wide. Many of the business structures are large, solid, and imposing, and there are many elegant and costly private residences. The city has had a very rapid growth, the population increasing from 770 in 1810 to 79,750 at the last census, when there were 15,639 families and 14,688 dwellings. Of the 79,570 inhabitants, 35,381 were of foreign birth, and 2,235 colored. The larger portion of the foreigners were Germans. The principal park of Detroit is the "Grand Circus," and it is the center from which the principal avenues radiate. The plan of the city leaves a number of small triangular parks, where the streets intersect each other at oblique angles. The "Grand Circus" is semicircular and divided by Woodward avenue into two parts, each adorned with a fountain. The "Campus Martius" is a plot of ground 600 ft. long and 250 wide, crossed by two avenues. Facing it on one side is the city hall, a fine structure of sandstone, 200 ft. in length by 90 ft. in width, which cost \$600,000. In front of the city hall is a monument to the soldiers of Michigan who fell in the war of the rebellion; and facing the Campus Martius on the n. is an opera house, a large and fine building. The United States custom-house and post-office, a large building of stone, is on Griswold street. The largest church edifice is the Roman Catholic cathedral, but there are several of other denominations which are fine specimens of architecture. The Roman Catholic convent of the Sacred Heart is a large and handsome structure. The Michigan Central freight depot is 1250 ft. long and 102 ft. wide—a single room, covered by a self-supporting roof of iron; and near it stands a grain elevator with cupola, commanding a fine prospect. The house of correction is also a very handsome building, erected at a cost of \$300,000, with a capacity for 450 inmates. There are two beautiful cemeteries, one on the w., the other on the e. side of the city; and besides these several smaller ones belonging to different religious sects. Nearly a dozen lines of street railroad intersect the different parts of the city, and ferries-boats ply constantly between it and Windsor on the Canada side of the river. There are numerous lines of steamers with elegant and commodious boats running to different points on the lakes. Eight great lines of railroad center here, connecting Detroit with all parts of the United States and Canada. The foreign commerce of the city is almost exclusively with the adjoining British possessions. For the year ending June, 1873, the exports amounted to almost \$3,000,000, the imports to about \$2,000,000. In the second year there were entered and cleared 1949 American and 1522 foreign vessels, with a capacity of about 8,000 tons. The coasting trade in the same year, by steam and sailing vessels, amounted to over 773,000 tons. The number of sailing vessels belonging to the port was 188, of steamers 120. The exports for the most part consist of corn, oats, wheat, lumber, cotton, hogs, bacon, and lard. Large quantities of domestic produce, from Michigan and states farther west, pass eastward through D., the chief articles being flour, wheat, corn, oats, barley, apples, butter, hides, hops, dressed hogs, pork, beef, wool, and sheep. The trade in lumber is very large, the receipts in 1872 being 76,947,000 ft., of which less than 5,000,000 ft. was from Canada. About 60,000 cattle, valued at about \$2,500,000 were sold in D. in the same year. The manufactures have developed rapidly and are very extensive. There are numerous foundries and blast-furnaces, copper-smelting works, locomotive and car works, safe factories, furniture establishments, iron-bridge works, brick-yards, flour-mills, tanneries, breweries, distilleries, and tobacco and cigar factories. The capital invested in banks of discount was \$2,250,000 and there were 4 savings banks with deposits of about \$400,000. There are also fire, marine, and life insurance companies doing an extensive business. The cash value of property in 1872 was estimated at \$78,718,913. The police and fire departments are well organized. The city is abundantly supplied with water from the Detroit river by works valued at \$1,221,752. Hospitals and asylums abound. The public schools are well organized and efficiently managed. The Roman Catholics and some of the Protestant sects have schools of their own. The Detroit medical college was organized in 1868, the homœopathic college, 1871. The public library contains 25,000 volumes; that of the young men's society 12,000; that of the mechanics' society 4,000. There are in the city 8 daily papers (3 of them German), 3 tri-weekly, 14 weekly, 7 monthly. There are 64 churches, of which 9 are Roman Catholic, the others being divided among the various denominations, of which the Baptists, Methodists, Presbyterians, and Lutherans are most prominent.

**DETTINGEN**, a village of Bavaria, circle of lower Franconia, on the right bank of the Maine; noted as the scene of a battle during the Austrian wars of succession. This conflict, in which George II. of England headed the army of the allies, while the duke de Noailles acted as commander of the French forces, took place on the 27th June, 1743, and was the last occasion in which a king of England appeared in person on the field. The army of the allies was composed of English, Hanoverians, Hessians, and some troops from the Low Countries, amounting in all to an active force of 37,000 men; while the French leader Noailles had an army of about 60,000. The former occupied a

valley extending from Aschaffenburg to Dettingen. Before the fight, Noailles threw 12,000 men into Aschaffenburg, and so made it impossible for his opponents to retreat with safety. The defile of D. in front of the allies was also held by De Grammont with 25,000 men, while Noailles himself, shifting his position on the Maine, so as to command with his batteries the flank and rear of the allies, rendered their position so critical that George resolved to force his way through the enemy. It was his only chance; and fortunately for him, De Grammont rashly and foolishly left his position, rushed over the morass and tivulet in his front, and engaged. At this moment, George, dismounting, placed himself at the head of the British and Hanoverian infantry, flourished his sword, and shouted: "Now, my boys, for the honor of England! fire; behave well; and the French will soon run!" Shock after shock from the impetuous French horse broke on the steady lines of infantry in vain, and at length George, forming his infantry into one solid column, advanced. Onward went the column, dense, steady, and overwhelming, breaking the squadrons of De Grammont, and driving horse and foot before them, until the enemy broke into promiscuous and bewildered retreat. Noailles's reserves were too late to be of any use: the allies had won the day. Many of the French were driven into the Maine, and so drowned; some were killed in the pursuit, which, however, was not prosecuted to any great extent. The loss of the French, in killed, wounded, and prisoners, was estimated at 6,000, and that of the allies at 2,000 men.

**DETVA**, a t. in the n.w. of Hungary, is situated in a deep valley, 20 m. e. of Altsohl. Pop. 31st Dec., 1869, 10,035.

**DEUCALION**, according to the Greek myth, was a son of Prometheus, grandson of Iapetus, and husband of Pyrrha. When Zeus had resolved to destroy the race of men by a flood, D. built and provisioned, by the advice of his father, an ark or ship, which he entered along with his wife. The flood came, and all Hellas was submerged. D. floated about for nine days, and on the subsidence of the waters, the ark rested on Mt. Parnassus. Other versions of the myth, however, make it rest on Mt. Othrys in Thessaly, on Mt. Athos, or on Mt. Etna in Sicily. D. and Pyrrha, according to one account, now offered up sacrifice to Zeus *Phrygius*, i.e., Zeus, the protector of fugitives, and prayed that he would repopulate the world, which he did; but the more common tradition was, that they went to the sanctuary of Themis for this purpose, and were told by the goddess that they must throw behind them the bones of their mother as they departed from the temple. Understanding by the "bones of their mother," the stones of the earth, they obeyed the injunction, and from those thrown by D. sprang up men, and from those by Pyrrha, women. D. built his first dwelling-place at Opus or Cynus. He is also said to have founded the sanctuary of Olympian Jove at Athens, and in later ages his tomb in the vicinity was long pointed out. D. had by Pyrrha several children, Hellen, Amphictyon, Protogeneia, and others. It was at one time extensively believed, even by intelligent scholars, that the myth of D. was a corrupted tradition of the Noachian deluge, but this untenable opinion is now all but universally abandoned. The myth is a comparatively late one, being mentioned neither by Homer nor Hesiod.

**DEU'EL**, a co. in e. Dakota, on the Minnesota border, as yet unsettled. It is watered by a number of lakes, and by affluents of the Big Sioux and Minnesota rivers.

**DEUS EX MACHINA**, an expression borrowed from the classical theater. In conformity with the popular mythological beliefs of their age, the tragic poets of Greece, instead of bringing about the dénouement of their plots by natural means, had often recourse to a more expeditious mode—viz., the intervention of a god, who descended in a machine, and abruptly solved whatever difficulty barred the proper termination of the piece. As examples of the *Deus ex Machina*, take the appearance of Hercules in the *Philoctetes*, and of Diana in the *Iphigenia in Tauris*. In modern tragedy, when a person or incident is introduced arbitrarily, *forced*, as it were, into the conduct of a plot, merely to remedy some inartistic negligence in its construction, or to save the author the labor of further ingenuity, such a contrivance is metaphorically called a *Deus ex Machina*. In modern comedy, the rich old uncle who suddenly comes home from the West Indies, and rescues the young couple (hero and heroine) from their dreadful pecuniary embarrassment, serves exactly the same purpose. When a savant or philosopher cannot explain some fact of nature by any known law, and has recourse to the supposition of the direct and immediate action of God, his assumption is also, termed by analogy a *Deus ex Machina*.

**DEUTERONOMY** (Gr. *Deuteronomion*, i.e., the second law) is the name given by the Septuagint translators to the 5th book of the Pentateuch, because it contains a repetition of the laws which had been already promulgated. It is commonly presumed to have been written by Moses himself, with the exception of the last four chapters, which narrate the closing events in the life of the great law-giver. Many critics, however, affirm that the entire book itself in its present form is post-Mosaic. The repeated allusions to the kingdom, the prophethood, the temple at Jerusalem, places in Palestine which Moses never saw, and could not have known, as well as various other particulars far too numerous to specify, are held to render it probable that D. is a late rescension and enlargement of some Mosaic abridgment of the previous portion of the Pentateuch.

Even in regard to the legislation, it differs materially from the Sinaitic code contained in the previous books. There are not only *deviations* from the latter, but also *additions* and *discrepancies*, suggesting another hand. The language, too, has late peculiarities. Ewald, Riehm, Bleek, Davidson, etc., fix the date of its composition about the middle of the 7th c. B.C.—See Davidson's *Introduction to the Old Testament*, vol. i., pp. 341–408.

DEUTERONOMY (*ante*) is the English title of the fifth book of Moses, derived from the Greek translation, and signifying “repetition of the law.” It well expresses the general scope of the book, which is a review of the 40 years in the wilderness, including the laws which had been given, and the events which had occurred. Whatever may have been the time occupied in writing it, the uttering of it to the people began two months before the end of the 40th year. To the arguments advanced by some writers that it was not written by Moses, the following answers (among others) have been given: 1. These writers are not agreed among themselves. The older of them affirm that D. was written long after the other books of the Pentateuch; the newer school pronounce it the quarry from which the materials of the others were taken. This conflict of opinions at least precludes the assertion that its style betrays its late origin. 2. The alleged anachronisms, discrepancies, and difficulties admit, for the most part, of easy and complete explanation on the supposition that Moses was the author. 3. The unanimous and unwavering testimony of the ancient Jewish church and nation is that Moses was the author of the book. This is testimony against themselves, as it involves the admission that their sufferings as a nation were divine judgments on their sins. Consequently, their possession of the book and acknowledgment of it as a writing of Moses can be rationally accounted for only on the supposition that the generation in the wilderness received it from his hand. At no subsequent period could it have been imposed on them as a law which had been given them in the wilderness, under acknowledged obligation to which they had always lived, and for the transgression of which they had been punished in the past, and would be in the future. And as no generation, after the settlement in Canaan, could have been persuaded to receive it for the first time, so to every subsequent generation the temptation became stronger, if it were possible, to deny and reject its authority. 4. It had, in a remarkable manner, the attestation of the apostles and of Christ. Peter and Stephen quoted from it to large assemblies of Jews, as truly the words of Moses; Paul cites it in writing to Jews at Rome; and Christ drew from it, as the word of God, his answers to all the temptations of Satan.

It contains: I. A review of the history from Horeb to Kadesh; from Kadesh to the land of the Amorites; of Moses' own transgression, his exclusion from Canaan, and the appointment of Joshua in his stead; of the reception of the law at Horeb, spoken by the voice of God, and written by him on tablets of stone. The review of these events is made the ground of an earnest exhortation to reverence, obedience, and gratitude to God. II. A review of the laws: 1. Of the moral law, and of the effect produced on the people by the proclamation of it; of the first and second commandments especially, with exhortations to obedience, and warnings against transgression; and, again, of the whole law, with a renewed appeal for obedience in view of past experience; of future blessings promised, and wrath threatened. 2. Of laws for the regulation of religious ceremonial and of personal life; for the abolition of idolatry and the observance of divine worship; against false prophets, idolatrous cities, and personal disfiguration as a sign of mourning; concerning clean and unclean animals, the year of release, the annual feasts, judges and justice; and against groves and images. 3. Of the strictly judicial law in numerous details. III. Provision for the confirmation of the law by writing it on large stone tablets to be set up on Mt. Ebal, with the uttering of curses on transgressors, and of blessings on the faithful. This is followed by an earnest call for consecration of heart and life to God. Pardon is promised to the penitent, and the choice of life or death is set before all. IV. The close of the official and personal history of Moses. He appointed Joshua to succeed him, charging him to be faithful and courageous; delivered a copy of the law to the priests and Levites to be placed by the ark of the covenant, and read publicly to the congregation every seven years; and as he had commenced the journey through the wilderness with a triumphant song, so now he closed it with songs of review, warning, and prophetic blessing on the tribes. The account of his seeing the promised land, the record of his death and burial, and the testimony to his greatness as a prophet and servant of the Lord, were added, probably, by Joshua, as the appointed finisher of his work.

DEUTSCH, EMANUEL OSCAR, was b. of Jewish parents, at Neisse in Silesia, in 1829. His education was begun by an uncle, to whom he owed his mastery of the whole range of Hebrew and Chaldean literature, and was finished at the university of Berlin. In 1855, he came to England to fill an appointment in the national library; and from this time he was known for his labors in the British museum, and his efforts to promote the study of the Semitic languages. He is best known to the outside world by his brilliant article on the *Talmud* in the *Quarterly Review*, to which he also furnished an article on *Islam*. He wrote excellent articles on the *Targum* and the *Samaritan Pentateuch* for Dr. Smith's *Dictionary of the Bible*, and was a valued contributor to the present work, for which he wrote nearly 200 articles. The best monument of his official work in the national

library is to be found in the *Phœnician Inscriptions*, edited by Mr. Vaux, to whom D. rendered most valuable assistance. D. died in 1873 at Alexandria, whither he had gone in the pursuit of health. His engrossing public duties and comparatively short life prevented D. from fulfilling the dream of his life, an elaborate work on the *Tabnud*. A volume of his literary remains, with a sketch of his life, was published in 1874.

**DEUTZ.** See COLOGNE.

**DEUTZIA**, a genus of shrubs of the natural order *Philadelphaceæ*, natives of the n. of India, China, and Japan, some of which are now reckoned among the favorite greenhouse plants of Britain, in some situations even enduring the open air. They produce abundance of beautiful white flowers. The leaves of *D. scabra* are so rough with siliceous hairs, that they are used by joiners in Japan for polishing wood.

**DEUX-PONTS** (Ger. *Zweibrücken*), a t. of Rhenish Bavaria, picturesquely situated among wooded heights on the Erbach, near its junction with the Serre, 34 m. w.n.w. of Landau. Deux-Ponts, which owes its name to the two bridges which there cross the Erbach, is well built, and has among its principal buildings a Lutheran cathedral, also the remains of an ancient ducal palace, now used as a Catholic chapel. Its manufactures are woolen and cotton cloth, hardware, leather, and tobacco. Pop. '75, 9,349.

Deux-Ponts, or, in Latin, Bepontium (whence the name Bepontine given to the edition of Greek and Latin classics here printed by a society of scholars in 1779), is not mentioned in history till 1197, and was then in the possession of counts of Deux-Ponts. After various changes of masters, it finally came into the possession of Bavaria.

**DEV**, or **DEW** (Persian), and **DEVA** (Sanskrit); kindred names; in Persian applied, according to Zoroaster, to a race of demons created by Ahriman, and subject to his commands. The Sanscrit word in Hindu mythology signifies "gods."

**DEVAPRAYAGA**, a t. in India, remarkable chiefly for its situation, stands in the fork of the Aluknunda and the Bhagerettee, whose united waters immediately assume the name of Ganges. It is in lat. 30° 8' n., and long. 78° 39' e., belonging to the protected state of Gurwhal; and its elevation above the point of confluence is 313, and above the sea, 2,266 feet. Marking, as it were, the source of the sacred river, D. is a favorite place of pilgrimage for the Hindus; and, in fact, its only permanent pop. consists of about 1000 Brahmans from the Deccan. In connection with the holy character of the locality, are two ancient temples, a flight of steps in the rock down to the very brink of the mingled streams, and three basins excavated in the solid stone a little below the level of the surface of the current. The town was much shattered by an earthquake in 1803, but was subsequently repaired at the expense of Scindia, the Mah-ratta chief of Gwalior.

**DEVELOP**, in algebra, to write out in full the operations set down in symbols. In geometry, to develop a curved surface is to produce on a plane an equivalent surface, as by rolling the curved surface so that all parts shall successively touch the plane.

**DEVELOPMENT OF DOCTRINE** signifies the modifying process through which Christian or philosophical opinion passes in its transmission from age to age. At first comparatively simple in its expression, doctrine has a tendency to become more complicated and technical in structure as argument is exercised upon it, and the spirit of controversy excited. The difference between the doctrinal statements in the Pauline epistles and the earlier creeds, such as that of Nicaea, the elaborate expositions of the mediæval theologians, and again of the Protestant theologians of the 16th and 17th centuries, is a difference at once appreciable by the theologian, as it is full of interest to him. There is, beyond doubt, at these several points in the history of the church, a certain growth or extension of Christian opinion called forth by, and corresponding to, the exigencies of the times. This is what is meant by the development of Christian doctrine, and the name denotes with sufficient propriety an unquestioned series of phenomena.

It is true that the idea of development in doctrine is one of modern origin, unknown to the earlier dogmatic ages of the church. But this merely proves that it is only in recent times that the history of the church has been reviewed in a critical and philosophical spirit. The idea of development is modern in its application to science altogether, and especially to the science of history. The ground upon which it is vindicated, in its application to Christian doctrine, is, that this doctrine is not a mere repetition of Christian truth in the language of inspiration, but really the rational or argumentative exposition of this truth. It represents this truth as it appears to the Christian reason in different ages. It is the expression of what has been called the *Christian consciousness* working in contact with the text of Scripture. The Nicene doctrine of the Trinity, for example, is the definite explanation which the Christian reason of the 4th c. gave to the undefined and general expressions of the gospels and epistles as to the relation of the Father and the Son. The doctrine of the atonement, as a *satisfaction* to God for the sins of the world, is first clearly and explicitly unfolded by St. Anselm in the 11th century. It is not meant that the elements of either of these doctrines are not to be found in Scripture, or that they are the product of human ingenuity; it is only affirmed that the scriptural elements in the one case and the other, were first clearly and argumentatively unfolded by the ingenuity of the Christian reason at these different times. The very idea of *doctrine* implies the employment of reason, and the exercise of inquiry and

argument upon the divine truth of Scripture. It is this truth analyzed and reflectively given forth—not the mere equivalent of Scripture, but something derived from it by Christian investigation and culture. Such a process of investigation and culture is necessarily variable and progressive. The divine fact remaining the same, the human explanation or doctrine of it may and does greatly vary. The course of this variation—the rising and falling of the human apprehension of the meaning of Scripture—is the development of doctrine.

This view is to be distinguished from that which characterizes the extreme subjective school of German theology. According to this school, Christian doctrine is nothing else than the expression of the Christian consciousness at any time. Scripture maintains no permanent or authoritative relation to it. It is all progress—a continued flux, without any normal standard or expression. Scripture may be its primary expression, but it may leave its fountain-head, and in the course of time issue in developments not necessarily bound to Scripture. But according to the view above set forth, Scripture remains the absolute and complete revelation of Christian doctrine, which is continually unfolded, but never exhausted by inquiry—beyond which right reason and truth never travel. The Christian revelation not only admits of, but demands constant criticism, as the means of unfolding more comprehensively and perfectly its contents, but it remains in itself the consummate expression of all spiritual truth; and it is this very peculiarity of the Christian revelation that makes its contents capable of continual and ever fresh development. It is just because its substance is divine, that its doctrinal expressions never cease to interest and to answer to the necessities of successive times. Other religions, while capable of development, reach a point where they cease to have any further living meaning, and pass on the one hand into mere popular mythology, or into an esoteric priestly tradition. They become transmuted into poetry or some ordinary product of philosophical speculation. Civilization overtakes and supplants them. But it is of the distinguishing divine character of Christianity that its doctrines possess a vital ever-renewing power, capable of adaptation to the highest forms of human civilization, and full of enlightenment and guidance to the most advanced intelligence. The development of Christian doctrine, therefore, is not merely a subject of curious and important study in the past, but of great and significant influence for the present and the future.

**DEVELOPMENT OF THE EMBRYO.** Harvey laid down the principle, in opposition to the views of those who believed in the doctrine of spontaneous generation, that all animals are produced from eggs (*omne vivum ex ovo*); and more recent researches have fully confirmed this view, if we are allowed to accept the modes of reproduction known as *gemmiparous* and *fissiparous*, or multiplication by buds and propagation by division, and the series of cases in which the offspring never resemble their parents, but the original form reappears in the second generation, and which are consequently said to present the phenomena of *alternate generation*. These exceptional cases occur only in very low forms of animal life, and, as a general rule, in retracing the phases of animal life, we arrive at an epoch in which the incipient animal is inclosed within an egg. It is then termed an *embryo*; and the modifications which this embryo undergoes before the young animal has an independent existence, are included in the general term which stands at the head of this article. Before embryology was properly studied, all animals were arranged under two great heads—the *oviparous*, which lay eggs; and the *viviparous*, which bring forth their young alive. We now know that viviparous as well as oviparous animals are produced from eggs—the only difference in this respect being, that their eggs, instead of being laid before the development of the embryo, begin to undergo their early changes in the body of the mother.

The egg has generally a more or less spherical form; the eggs of birds have, however, the form of an elongated spheroid, narrow at one end, and hence the origin of the word *oval*. Some eggs, as, for instance, those of certain insects (e.g., the podurella), are furnished with projecting filaments; others have a sculptured surface; and others, again, have peculiar forms, being cylindrical or prismatic. A simple sphere is, however, the normal form.

The egg originates within organs termed *ovaries*, peculiar to and characteristic of the female, except in those cases in which both male and female reproductive organs are associated in the same individual. These ovaries are glandular bodies, and are usually situated in the abdominal cavity. So long as the eggs remain in the ovary, they are very minute, and in this condition they are called *ovarian* or *primitives eggs*. They are identical in all animals, being, in fact merely little cells, containing yolk substance, in which is inclosed the germinative vesicle and the germinative dot. The yolk itself, with its membrane, is formed while the egg remains in the ovary; it is afterwards inclosed in another envelope, the shell-membrane, which may either remain soft, like parchment, or may be surrounded by calcareous deposit, as we observe in birds' eggs. The number of eggs seems to increase in proportion as we descend the animal scale, the eggs laid by a bird being far fewer than those laid by a fish, while these again are less than those laid by some insects.

The egg, when it has attained a certain degree of maturity, leaves the ovary. This step in the process is termed *ovulation*, and must not be confounded with the laying or

deposition of the eggs, which is their subsequent expulsion from the abdominal cavity, through (in most cases) a special canal termed the *oviduct*. Ovulation takes place at a definite period of the year in most of the lower animals, and seldom until the animal has attained its full growth. In general, ovulation is repeated for a number of years consecutively, usually in the spring; sometimes, however, it occurs but once during life, as in most insects, which die soon after the process is accomplished.

After leaving the ovary, the eggs are either discharged from the animal, and undergo their further changes in the external world, or they continue their development within the body of the mother, as is the case in some fishes and reptiles (as sharks and vipers), which have consequently been named *ovoviviparous* animals; or, in the case of the mammalia, they are not only developed within the body of the mother, but, except in the case of the marsupialia and monotremata (q.v.), become intimately united to her by the intervention of certain temporary structures—namely, the placenta and umbilical cord. This mode of development is termed *gestation*.

The development of the embryo does not always take place immediately after the egg is laid, and a considerable time may elapse before it commences. Thus, the first eggs laid by the bird do not begin to undergo development until the whole number which is to constitute the entire brood is deposited; and the eggs of most insects are laid in the autumn, and remain unchanged till the following spring. During this time, the vital principle is dormant. See DORMANT VITALITY. In the case of birds and reptiles, a considerable degree of warmth is requisite for the process of development. In birds, the act of *incubation*, or “sitting,” supplies the necessary amount of heat; and in reptiles, the eggs are hatched by exposure on sands to the sun’s rays, by their being deposited in warm dunghills, etc.

In the composition and structure of a newly-laid hen’s egg—and of course the description equally applies to the egg of any other bird—we have exteriorly the shell, whose hardness is due mainly to carbonate of lime, and which is lined by a double membrane, the shell-membrane; then there is an albuminous substance, the *white*, in which several layers may be distinguished; within this, we find the *yolk*, inclosed in its membrane; and in the midst of the yolk there was, before it was laid, a minute vesicle, the *germinative vesicle*, containing a still smaller one, the *germinative dot*. The most conspicuous of these parts—namely, the shell and the white—are not physiologically essential, and are wanting in the eggs of most animals lower than birds; while the yolk, the germinative vesicle, and the germinative dot, are found in the eggs of all animals; and it is from these parts, and these only, that the germ is formed. The *yolk* or *vitellus* is the most essential part of the egg. It is a viscid fluid, sometimes opaque and colored, as in the eggs of birds, and sometimes transparent and colorless, as in the eggs of many fishes and mollusks. The microscope shows that it is composed of an accumulation of granules and oil-vesicles. The yolk is surrounded by a very thin skin, termed the *vitelline membrane*. In some insects, this membrane forms the outer coat of the egg.

The *germinative vesicle* is a cell, situated in the young egg near the middle of the yolk; it contains one or more minute spots or nuclei, termed the germinative dots, which themselves contain smaller nucleoli. The *albumen* or *white* of the egg is a viscid and colorless fluid, which coagulates and becomes opaque on the application of a temperature of 146° F. Although it forms a large part of the egg of the bird, it is of very trifling importance in reference to the development of the embryo. It is not formed in the ovary like the yolk, but is secreted by the oviduct, and deposited round the yolk during the passage of the egg through that canal; hence, when there is no oviduct, the albumen is generally absent. In birds, it consists of several layers, one of which, forming the *chalazæ*, presents a coiled, rope-like appearance. The albumen in this part is thicker than that which lies more externally. The albumen is bounded externally by the *membrana putaminis*, or *shell membrane*, which splits into two layers, leaving a space at the broad end, filled with air; in birds, and in some reptiles, this membrane is covered by the calcareous shell; in most cases, however, it continues membranous, as in the eggs of the mollusks, most crustaceans, and fishes, frogs, &c.; and sometimes it is horny, as in the sharks and skates.

In order to understand the successive steps of embryonic development, we must remember that the whole animal body is formed of tissues, the elements of which are cells. See CELLS. While in the full-grown animal these cells have undergone such modifications as often hardly to present any indication of their primary form; in early embryonic life, the cells, which originate within the yolk, present a definite form and consistence. These cells we shall presently see become transformed into the blood, bone, muscle, etc., of the young animal. At the commencement of the process of development, the yolk, which previously was a mass of uniform appearance, gradually presents certain alterations. Some portions become more opaque, and others more transparent; and the germinative vesicle, which was in the center, rises to the upper part of the yolk, where the germ is to be formed. The yolk at the same time undergoes a peculiar process of segmentation. It is first divided into halves, forming distinct spheres, which are again continuously and regularly subdivided into two, till the whole or a part of the yolk assumes the appearance of a mulberry, and is known as the “mulberry mass.” In fishes, the class of animals whose development we shall specially follow in this article, the segmentation is only partial, the divisions of the yolk not extending into its whole

mass. This process leads to the formation of a *germ*, which usually rises above the yolk in the form of a discoid protuberance, which has received the various names of germinative disk, proligerous disk, germinal membrane, etc., and which is composed of minute cells. This disk enlarges till it embraces the whole, or very nearly the whole, of the yolk. At this early period, the germ consists of a single layer of very minute cells of uniform appearance; it soon, however, increases in thickness, and in vertebrate animals separates into various layers, which gradually become more and more distinct. The upper layer is termed the *serous* or *nervous layer*, and from it are subsequently developed the principal organs of animal life—such as the bones, muscles, brain and nerves, etc. The lower layer gives origin to the organs of vegetative life, and especially to the intestines and chylopoietic viscera, and is called the *mucous* or *vegetative layer*; the cells of which it is composed are larger than those of the serous layer. Between these layers there is, in the vertebrata, an intermediate layer, giving rise to the organs of circulation and to the first-formed blood, and hence termed the *vascular layer*.

At a very early period the germ undergoes modifications of form, varying with the department of the animal kingdom to which it belongs. Thus, in the articulatæ (insects, crustaceans, etc.), the germ is divided into segments, indicating the transverse divisions which occur in the adult animal; while the germ of vertebrate animals displays a longitudinal furrow, marking the position which the vertebral column and spiral cord are to occupy. The development of this furrow is highly important. At first, the furrow is very shallow, and a minute transparent band appears under it, called the *primitive stripe*. The walls of the furrow consist of two raised edges formed by a swelling of the germ on both sides of the primitive stripe. As these walls increase in height, their summits approach each other; and after a time they unite and convert the furrow into a closed canal, which is soon filled with a fluid from which the brain and spinal cord are subsequently formed.

The primitive stripe is gradually developed into a cartilaginous structure, termed the *chorda dorsalis*, which is the representative of the back-bone. In the meantime, the margin of the germ continues to extend over the surface of the yolk, until at length the latter is entirely closed in a cavity thus formed by the germ. In this lower cavity, the intestines and other organs of vegetative life are subsequently developed.

In all classes of the animal kingdom, the embryo rests upon the yolk, and covers it like a cap; but the direction by which its edges approach each other and unite to form the lower cavity, is very different in different kinds of animals, and is highly distinctive in reference to zoological classification. In all the vertebrata, the embryo lies with its face or ventral surface towards the yolk, and thus the suture or line at which the edges of the germ unite to enclose the yolk, and which in mammals forms the navel, lies in front. Another suture is found along the back, arising from the folding together of the upper surfaces of the germ, to form the dorsal canal. In the affection known as *spina bifida*, this suture is incomplete. In the articulatæ, the embryo lies with its back upon the yolk; in the cephalopoda, the yolk communicates, as in the vertebrata, with the ventral surface of the body, but no dorsal canal is formed in them; and in the other departments of animal life, we find special and characteristic relations between the embryo and the yolk.

The development of the embryo of vertebrate animals is best observed in the eggs of fishes, as from their transparency they do not require to be cut open; and with due care the whole series of embryonic changes may be observed upon the same individual, and the succession of appearances of the different organs may be ascertained. Prof. Agassiz has carefully examined and depicted the principal phases of development in the white-fish, which belongs to the salmon family, and we shall endeavor to give his chief results. The egg when laid is spherical, about the size of a small pea, and nearly transparent. It contains no albumen, and the shell-membrane and the membrane of the yolk seem fused into one. In a few hours after it has been laid, provided it has come in contact with the fecundating fluid of the male, a separation between these two membranes takes place, in consequence of the absorption of water, by which the size of the egg is increased. Between the shell-membrane and the yolk there is now a considerable transparent space, corresponding in position to the albumen of birds' eggs. Oil globules are scattered through the yolk, but soon arrange themselves in a stratum or disk towards the upper part, where a swelling, in the shape of a transparent vesicle, begins to show itself. It is composed of very delicate and minute cells, and is the germ in its earliest stage. As the germ increases, and has a larger surface in contact with the yolk, we notice a depression on its upper part, and soon after a second furrow appears at right angles to the former, so that the germ now presents four elevations. A continuous subdivision of this nature goes on during the second and third days, until the germ is divided into numerous minute spheres, which form what is termed the mulberry mass. This appearance, however, does not long continue; at the end of the third day, the fissures disappear, and the germ continues to extend as an envelope around the yolk, which it at last entirely incloses.

On the tenth day, the first outlines of the embryo begin to appear, and we soon distinguish in it a depression between two little ridges, whose edges approach till they form a canal. At about the same time, an enlargement at one end of the furrow is

observed, which is the rudimentary head, in which may soon be distinguished traces of the division of the brain corresponding to the organs of sight, hearing, and smell.

Towards the thirteenth day, we see a transparent cartilaginous cord (the *chorda dorsalis*) in the position afterwards occupied by the backbone, composed of large cells, in which transverse divisions are forming. In some fishes, as the sturgeon, this cartilaginous or embryonic state is persistent through life, and no true osseous vertebral column is ever formed. The rudiments of the eye soon appear in the form of a fold in the external membrane of the germ, in which the crystalline lens is afterwards formed. At the same time we see at the posterior part of the head an elliptical vesicle, which is the rudimentary ear. At this period, the distinction between the upper (serous) and lower (mucous) layers of the germ is best traced; all the changes which have been mentioned occurring in the upper layer.

At or soon after the seventeenth day, the lower (or mucous) layer separates into two laminae, the inferior of which becomes the intestine. The heart at about the same time appears in the form of a simple cavity, in the midst of a mass of cells belonging to the middle or vascular layer. As soon as the cavity of the heart is closed in, regular motions of contraction and expansion are observed, and the movement of blood-corpuscles within it is seen.

It is not till the thirtieth day that any traces of a circulation of the blood are manifested; we then notice two currents, one running towards the head, and the other towards the trunk, with corresponding returning currents. The traces of the liver are now seen. The embryo begins to liberate itself at both extremities from the yolk, the tail first becoming free, and moving in violent jerks.

The embryo, although still inclosed in the egg-membranes, now unites all the essential conditions for the exercise of the functions of animal life: it has a brain, an intestine, a pulsating heart, and circulating blood, and a limited amount of spontaneous motion; but the forms of the organs are still incomplete, nor have they acquired the precise shape characterizing the class to which it belongs. The embryo is as yet only a vertebrate animal in general, and might be taken for that of a frog as well as for that of a fish.

Towards the close of the embryonic period, after the fortieth day, the embryo acquires a more definite shape: the jaws protrude; the nostrils approach the end of the snout; divisions are observed in the fin-like structure which surrounds the body; the anterior extremities, which were mere knobs, become rudimentary pectoral fins; and, finally, the gill-openings appear, so that the fish-type is now obvious. In this state, the young white fish escapes from the egg about the sixtieth day after it is laid; but its development is still incomplete. We cannot yet tell to what genus the fish belongs. The gill-covers are not yet formed, there are no teeth, the mouth is below instead of at the most projecting part of the head, and the fins have no rays. The remainder of the yolk is suspended from the belly in the form of a bladder, but it daily diminishes in size, till it is at length completely absorbed by the animal. The duration of these changes varies extremely in different fishes; some accomplish them in a few days, while in others, months are required.

In frogs and all the naked reptiles, the development is very similar to that of fishes; in the scaly reptiles (snakes, lizards, turtles), and in birds, there are peculiar membranes surrounding and protecting the embryo during its growth, termed the allantois and the amnios; and in mammals there are additional complications of structure, which it would be impossible to describe clearly without occupying more space than could be allotted to a subject of this nature. For further information on this subject, we may refer to the various writings of Agassiz, especially his *Lectures on Comparative Embryology*, and his *Comparative Physiology*, from which this article is mainly drawn, and to Carpenter's *Comparative Physiology*.

**DEVELOPMENT IN PHOTOGRAPHY**, the process which immediately follows exposure, and which renders the picture visible in all its details. It consists in the precipitation or deposition of *new material* on that portion of the sensitive surface which has been acted on by light; the same principle therefore prevails in all processes. This may be made clearer by reference to a few examples. In the daguerreotype process (q.v.), an iodized silver plate, after exposure in the camera, is exposed to the vapor of mercury; the vapor adheres to those portions of the plate which have undergone a peculiar molecular change from the action of light, but not to those parts unacted on. The lights of the picture are therefore "developed," or "brought out," by the acquisition of *new material*, i.e., mercury. A collodion negative is similarly "brought out" by the precipitation, by means of a deoxidizing agent, such as pyrogallie acid, or protosulphate of iron, on the *actinized* portion of the plate, of *new material*, composed of metallic silver and organic matter. A similar change takes place in the chrysotype process (q.v.), where the metallic salt with which the paper is impregnated is reduced to a state of proto-salt, which reacts through the decomposition of water, and causes the precipitation of *new material*, in the form of finely divided metallic gold, on the parts where light has acted. Other processes might be cited, but these are deemed sufficient to illustrate the principle stated above.

**DEVELOPMENT THEORY.** See SPECIES.

DEVENS, CHARLES, JR., b. Mass., 1820; graduated at Harvard, and admitted to the bar in 1841. He has been a member of the state senate; U. S. marshal for the district; served in the union army during the rebellion, being several times wounded; and is now associate justice of the Massachusetts supreme court.

DEVENTER, a thriving t. of Holland, in the province of Overijssel, situated on the Yssel, about 55 m. e.s.e. of Amsterdam. Tower-flanked walls surround D., which is further defended by a broad, deep ditch. The streets are narrow, but the market-places spacious. The principal buildings are the cathedral—a structure in the early Gothic style—the town-house, the court-house, and prison. From the ramparts, which are used as a promenade, there is a commanding prospect. The industry of D. consists in iron-founding, the manufacture of carpets, stockings, etc. Its gingerbread (called *Deventer kock*) is celebrated throughout Holland, and many thousand pounds are exported annually. There is a large trade in grain, butter, beer, firewood, etc. Pop. '76, 18,575.

DE VERE, MAXIMILIAN SCHELE, LL.D.; b. Sweden, 1820. He was in the Prussian diplomatic service, but came to the United States and was appointed to the chair of modern languages in the university of Virginia, 1844. Among his work are *Outlines of Comparative Philology*; *Stray Leaves from the Book of Nature*; *Studies of our English*; *The Great Empire*; *Wonders of the Deep*; *Americanisms*; *The English in the New World*; etc.

DEVEREAUX. See ESSEX, EARL OF, *ante*.

DEVIATION OF THE PLUMB-LINE, an effect observed near cliffs or mountains, which seems to show that the attraction of masses of earth deflect a perpendicular line. Similar effects have been observed on plains, whence it is argued that there must be hollows underneath, or masses of earth of different degrees of density.

DEVICE—from the middle-age Lat. *divisa*, a drawing or design—is a motto expressed by means of a pictorial emblem. The motto proper originated in the emblem, a written inscription coming to be added to the pictorial design, with the view of rendering the meaning more explicit. Devices thus consist of two parts—a pictorial figure called the "body," and a motto in words called the "soul" of the device. As early as the times of Æschylus, the "seven heroes before Thebes" all appear with devices on their shields; and the same is related by Xenophon of the Lacedæmonians and Sicyonians. In the middle ages, devices on coat-armor came into regular and formal use, and chivalry employed them in its courtly expressions of devotion to the fair sex. They were used both as charges on the shield and as crests. The only respect in which the device differs from other heraldic emblems is, that it has always some specific reference to the history, or circumstances, or position of the bearer. As an example: Louis XIII. of France had a falcon as a device, with these words: "*Aquila generosior aies*" ("A more generous bird than the eagle"), by which he meant to denote his own superiority to the emperor, whose device was an eagle. Devices, moreover, were generally borne only by the individual who assumed them, and not by the other members of his family or his descendants, like the crest or cognizance. They were often contrived to typify a special enterprise, the general character of the wearer, or even to designate his name—as the *mulberry* trees in the embroidered trappings of the horse of Thomas Mowbray, duke of Norfolk. On all festal occasions, they figured on triumphal arches, on banners and hangings. At a later period, it became customary to work devices into buildings; friezes and stained windows were often covered with them. This practice has recently much gone out, at least, in its original form. See Radowitz's *Die Devisen und Motto des spätern Mittelalters* (Stutt. 1850).

DE VIGNY, ALFRED VICTOR, Comte, 1797–1863; b. France; poet and novelist. Having been in the army 13 years without seeing active service, he resigned. He had already published several poems, and being in pecuniary ease (having wedded a rich English lady) he started in earnest on his poetical career contemporaneously with Victor Hugo and Lamartine. De Vigny published a volume in 1822, and in 1824 came *Eloa*, a poem of delicate fancy, the story of a sister of the angels. Soon afterwards he published *The Deluge*; *Moses*; *Dolorida*, etc. In 1826, appeared *Cinq Mars*, a historical romance of a conspiracy under Louis XIII. This had great success. In 1829, he translated *Othello* for the Parisian stage, and in 1836, made a drama of the romantic life of Chatterton, the English boy-poet. His best prose work is *Stello ou les Diables bleus*, issued in 1832. His last effort was *Poëms philosophiques, ou les Destinées*, part of which was published after his death.

DEVIL, or SATAN (Gr. *diabolos*, "false accuser;" Heb. *satan*, "adversary"), designates in the Old and New Testament a mighty spirit of evil who has, during unknown ages, ruled over a kingdom of evil spirits, and is in constant and restlessly active opposition to God. This belief, however, was very gradually developed in the Jewish mind; and it is beyond all question, that it acquired clearness and prominence through extra-national influences. In England, the "doctrine of Satan" has hardly received any critical treatment at the hands of scholars; but in Germany, the subject has been most learnedly investigated. The conclusions at which some of the profoundest Biblical scholars of the continent have arrived, and even the principles on which they proceed.

may be rejected by us, but a brief account of their method of historical analysis may be neither uninteresting nor uninstrucive. The older Hebrews, it is said, who lived before the period of the Babylonish captivity—judging from the silence of Scripture—knew nothing, and certainly taught nothing, of evil spirits in the later sense—i.e., of beings separated from God, who were evil in the essence of their nature, and worked evil only. *Moral* evil was rather looked upon as properly the act of man; *physical* evil, or adversity, on the other hand, as punishment merited through sin, and inflicted by a just and holy God, who was thus necessarily conceived as the true source of all calamity. The angels who foretold God's purposes, and executed his will, however great might be the physical evil they occasioned, are never accused of *moral* evil. Even in the Mosaic account of the seduction of Eve, there is nothing to induce us to believe that the author regarded the serpent other than as "the most subtle of all the beasts of the field," or that he meant to conceal under so plain a statement an allusion to Satan. It is probable, however, that at some early period in their history, the popular faith of the Jews, partly divorcing itself from its grand religious conceptions of the "one living and true God," and lapsing—as has everywhere been the case with the popular faith—into petty superstitions, had become familiar with the idea of certain fearful unearthly beings haunting wildernesses, similar to the fauns and satyrs of Greece, who might form the connecting-link in the later development of an actual demonism. Traces of this are clearly visible in the Pentateuch. The Hebrew word *seirim*, occurring in Leviticus xvii. 7, which our translators have rendered "devils," means only "hairy ones." Now, the Egyptians worshiped the *he-goat*, and the Hebrews partook, as we know, of their idolatry. Therefore Moses in this verse, forbidding them to commit this sin in future, says: "They shall no more offer their sacrifices to *seirim*—i.e., to the Egyptian he-goats. The development of demonism was materially furthered during and after the Babylonish captivity by Medo-Persian influences. In those canonical books of the Old Testament which belong, in their present form, to the post-exilian period—i.e., the period subsequent to the exile—the Jewish conceptions of angels become more definite. They possess different ranks, names, and specific offices. They are the tutelary guardians and helpers of particular lands and peoples, but are everywhere in absolute dependence on God. And now we meet also, for the first time, with an angel called *Satan*, who, however, still figures as a minister of God, and along with the others appears in heaven before the throne of Jehovah, but with the function assigned to him of accuser and seducer. It is he who—1 Chron. xxi. 1 (*Chronicles*, it should be mentioned, is considered by most critics, both orthodox and heterodox, to be the composition of Ezra, and therefore *post-exilian*)—stirs up David to number the people; while in the older Hebrew version (2 Sam. xxiv. 1) the same act is attributed to an angry God, the conception of Satan not *then* having clearly, if at all, presented itself to the Hebrew mind. It is Satan also who throws suspicion on the piety of Job, and with the permission of Jehovah, causes a series of misfortunes to befall him; while in Zechariah iii. 1, he is represented as "resisting" the angel of God, and as a false accuser of the high-priest Joshua. As yet, however, an evil nature is not *expressly* ascribed to him, but, what is much the same, it is assumed that he takes a pleasure in active evil. It is a purely arbitrary and untextual interpretation of Isaiah xiv. 12 ("How art thou fallen from heaven, O Lucifer, son of the morning!") that would force these words to refer to the fall of the D., or determine from them his name. In the Apocrypha, of which only a small part is Palestinian, the rest being either *Chalduco-Persian* (as, for example, *Tobias* and *Baruch*) or *Ægypto-Alexandrian* (as, for example, *Wisdom*) in its origin, the older Hebrew doctrine of misfortune coming from the angel of Jehovah is, so to speak, dismembered, and demons or evil spirits, in the New Testament sense of the term (*pneumata ponēra*), are for the first time mentioned (and in *Tobias* and *Baruch* frequently) as the authors of calamities. According to the representations of these writings, the evil spirits dwell, like the older Hebrew hobgoblins, in waste places, but associate themselves for the injury or destruction of men, enter into them as tormentors, and can be expelled only by magical or mysterious means. To this class of beings the heathen deities were reckoned to belong. But even here there is no mention of an *organization* or kingdom or prince of demons. The first trace of a *Diabolos* or D. proper (and one in all probability springing from a foreign source) shows itself in the Book of *Wisdom* (ii. 24), in relation to the seduction of Eve, where it is said that through the D. the necessity of death has come into the world.

In the period elapsing between the close of the Apocrypha and the appearance of Jesus, the Jewish ideas of angels, as well as of demons and the D., received an extensive development. This angelology and demonology, wholly foreign to the older Hebrew religion, was derived in all its essential characteristics from the system of Zoroaster, with which the Jews had become familiar by their long and close intercourse with the Persian empire during the exile, and subsequently. It was, however, impossible to transfer the *dualism* of Zoroaster into a creed so purely *monotheistic* as that of the Jews; this would have destroyed the foundation on which their entire history rested. Two beings, equally eternal, equally powerful, was an idea which no Hebrew—mindful of the glorious deliverance of his forefathers out of the land of Egypt, of the law given amidst the thunders of Sinai, of the manna in the wilderness, of the triumphs in Canaan, and the golden psalms of David—could for one moment entertain. But, on

the other hand, now that as a nation the Jews were become weak and of little account, hemmed in, and crushed by mighty and advancing empires, no conception could seem more true, or prove more consolatory, than that which permitted them to attribute their misfortunes to the agency of a demoniacal race, headed by a potentate only inferior to Jehovah himself. They could now believe that God had not forsaken his "chosen people." Thus, the dualism of Zoroaster suggested the kingdom and royalty of Satan, but the doctrine shaped itself in harmony with the national monotheism. The D. and his demons were represented as having been originally *angels*, who had fallen from their "high estate," been punished by God, and had therefore assumed a position of hostility, without, however, being able to materially frustrate the divine purposes. These opinions found an almost universal reception among the people, as well as among those Jewish theologians who, along with the Mosaic law, held oral tradition to be an authentic source of religious doctrine. Indeed, the only Jewish sect which rejected them, was that of the Sadducees, who considered them, as also the doctrines of the resurrection from the dead, of the Messiah, of the Messianic kingdom, of the last judgment, of rewards and punishments, and of angels and demons, to be new, outlandish anti-Mosaic myths and theories. This conflict of opinion among the Jews prevented their ideas of the D. and demons from obtaining, in spite of their broad diffusion, a dogmatic and systematic stability. The populace and the Pharisees believed fervidly in the existence of such evil spirits; but their conceptions had not only all the heat, but all the confusedness of superstition.

In this condition were the Jews when the New Testament lifts up the veil of oblivion that had partially dropped on the face of the nation more than two centuries before, and the light of history again falls brightly on its features. We now find a swarm of demons in Palestine. These unclean spirits, however, can be exorcised. When expelled from the soul of the demoniac, their proper home is "the abyss" (*Es ten abussom*, Luke viii. 31). According to the popular conceptions, therefore, we must suppose their dwelling to be a dark subterranean region, although, like the demons of the Old Testament, they inhabit also the earth and the air. They were not, as the Greeks and Josephus thought, the evil spirits of dead men, but had angelic natures (see Matt. xxv. 41), and formed a society governed by a chief, called Satan, Devil, Beelzebub, Belial, etc. He is now firmly seated in the popular imagination as a fallen angel; but as yet there is no hint of his having seduced his followers from their allegiance to Jehovah, or of their having fallen at the same time. This idea first appears in the book of Revelation, chap. xii., where mention is made of a great war in heaven between Michael and his angels on the one hand, and the D. and his angels on the other. "And the great dragon was cast out," says the writer, "that old serpent, called the Devil, and Satan, which deceiveth the whole world: he was cast out into the earth, and his angels were cast out with him." Whether or not these popular conceptions of the D. and his influence were materially or spiritually interpreted by Christ himself, it is impossible to say. He may either have accommodated his language to suit the popular mode of realizing the power of evil (a supposition which involves nothing unworthy of his sinless character), or (for this is the only other hypothesis compatible with a belief in his divinity) he may have intended to recognize the essential truth of that doctrine of an evil personality which the Jews derived from, or, at all events, developed under the inspiration of Zoroastrian ideas.

But whether Christ meant to accommodate his language to the popular conceptions or not, the primitive church assumed the personality of the D. as an unquestionable fact. The New Testament ideas on this point were not only greatly enlarged, but in many respects entirely changed, partly through the introduction of a considerable number of heathen notions, and partly through the dogmatic tendencies of the time, in consequence of which the various statements in the Bible regarding Satan and evil were *uncritically and unhistorically* heaped together, and a doctrine of Satanic agency elaborated *logically* but not *theologically*. Holding firmly to the belief of a Satanic kingdom of darkness opposed to Christ's kingdom of light, the majority of the early Christians ascribed all evil, physical as well as moral, to the D. and his demons; failures of the crop, sterility, pestilence, murrain among cattle, mental maladies, persecutions of the Christians, individual vices, heresies, astrology, philosophy, and especially the whole body of heathenism, with its mythology and religious worship. The heathen gods were believed to be conquered by the work of Christ, but not to be wholly powerless; they sank down into demons, and so a part of their mythology passed into the doctrine of the Devil. It was they who, as demons, meaning to deceive, uttered oracles, were present at sacrifices, and inhaled the sacrificial incense, whereby the notion gained ground that the demon-nature was ever growing more and more sensual and materialized—a notion that reacted again on the conception of hell, which soon began to be painted in coarse, earthly colors, blazing with eternal fire, through which blackened devils and scorched souls flitted in endless torment. From the gross materialism that now vitiated all conceptions of the D. and of demons, sprang the loathsome belief, common enough in the early church fathers, but during the middle ages exhibiting itself only in the superstitions of the vulgar—viz., of the carnal intercourse of devils with women. See WITCHCRAFT.

Concerning the fall of the "devil and his angels," opinions were long diverse. Some

supposed that it occurred through envy; others, through pride; and others again, through concupiscence and excess; some placed it before, and others after the seduction of Eve by the serpent. Several of the fathers (for example, Augustine) believed that man was created to fill up the gap which had been caused in the kingdom of Christ through the apostasy of Satan and those whom he had led astray. Meanwhile, the idea of the importance of the death of Jesus had been dogmatically elaborated. At first, Christians saw in that death a sacrifice, and in his blood a propitiatory power; but soon after, their thoughts reverted to the other scriptural representation of an actual victory over the D., a restoration of the Divine image in man, and the source and condition of holiness; whence was developed a very wonderful dogma concerning the devil. God having declared that whoever should transgress his law, should incur death and damnation; and man having done so, God's justice and veracity compelled him to keep his word. But inasmuch as Eve was beguiled into transgression, and fell as it were unwittingly, it did not seem for the honor or good of the Deity that rational beings, partakers also of his own spirit, should be lost through a trick of the fiend; wherefore Jesus offered himself to the D. as a ransom for the souls of men. The D. thinking "the *man* Christ Jesus" of more value than all the rest of the race put together, closed the bargain immediately. But deceived in his turn by the "appearance of flesh," he did not recognize the Deity concealed beneath it; and not being able to retain the latter (shrinking from it, in fact, horrified and dismayed) he lost *both*—Christ and man. The D. was, however, *actually* deprived only of Christians, in all other men he dwelt and ruled through the force of original sin. In consequence of this he was formally "banished" (until the 3d c.), not only from "demoniacs," but also from all converts from Judaism and heathenism to Christianity; and when the practice of baptism had shaped itself into the dogma, that it was "a necessary preliminary to holiness," exorcism, or "driving out the devil," became a Christian "art," exercised on all new-born children. Those who died unbaptized, were (by that ruthless logic that frequently marks a barbarous theology) sent to hell; for although *potentially* Christ's, the church had not yet rescued them from their satanic master, by the appointed rite, and so the conditions being unfulfilled, the D. carried off his prey. Yet the heart of humanity, stronger in its simple instincts than the most iron creed ever hammered out of the human brain, showed its holy presence even in so fearful a dogma; and although it could not deliver the lost infants from the region of eternal fire, it assigned them less painful pangs, and a less dreadful dwelling-place. But while the power of the D. over all not guarded by Christian faith and rites, was supreme; over those who were so guarded it was utterly weak. No Christian, not even the weakest, could be *forced* by him to do evil. Thus far had the "doctrine of the devil" been developed at the 8th c., and at this point it has essentially remained in the eastern or Greek church; but in the western it took yet another development. This was mainly occasioned by the writings of pope Gregory the great, who partly took up the popular notions himself, infused into them other then prevalent theological opinions, and elevated the result of the incongruous mixture to the dignity of Church doctrine. He calls the D. a "stupid beast," because he hopes for heaven, without being able to reach it, and entangles himself in his own net; but on the other hand, he admits him to have a *potentia sublimitatis*, and utters the profound idea that he cannot comprehend our thoughts. In these three notions lie the essential germs of the Germanic Faust-devil. The old German and Norse mythologies poured a flood of heathen fancies into the "doctrine of the devil." Even Ulfilas, at a much earlier period, had translated the New Testament word *daimon* or *daimonion* by *unheilthā*, i.e., she-devil or sorceress, because the old Germans believed in *female* demons, while the Christian *usus loquendi* contains no trace of such. The peculiarly German conception of a now malignant, now gentle *female* lives to this day in the German phrase, "The devil is beating his mother" (when rain and sunshine quickly alternate). In England and Scotland, too, the phrase is, or recently was current, "The devil and his dam." The Germans have also the proverb, "Where the devil cannot come, there he sends his grandmother." Soon, however, the word *diabolus*, in violation of the New Testament distinction between it and *daimon*, came to signify devils of every or any sort. The Gothic form of the word was *diabulus*, *diabūlus*; old Saxon, *drubhul*, *drubhal*, *diabol*; old High German, *diufal*, *tierval*, *tiubil*, etc. The dwelling of the D. was, of course, hell, which, however, according to old Germanic and Scandinavian notions, was placed in the dreary regions of the north. Although his mischievous powers are to be pretty well controlled till the coming of antichrist, when he expects to hold carnival, yet, like the ancient gods and demons; he occasionally appears on the earth. He then assumes at times a purely human form, but, like Vulcan, who was thrown down from heaven like himself, and the smith Wieland, of German mythology, he is somewhat lame. He is covered with a grey, green, or red cloak, like the Kobolds (q.v.) and dwarfs (q.v.), (the earth and house spirits of the suppressed heathenism); sometimes, also, he appears black and sooty, as befits his dwelling-place, and his opposition to a pure God. But as the old deities, both classical and German, possessed the power of transformation to a most remarkable degree, the D., through his relationship with these, inherited this power when they vanished from the scene. The form he most frequently assumed was that of an animal, approximating, in this respect, to the German forest-spirits and the Greek satyrs and fauns. At one time he shows the foot of a horse or goat with horns and tail; at another, he appears as a black horse, a he-goat, a

hog, a wolf, a hell-hound, a raven, a serpent, a worm, a dragon, or a fly. The conception of the power of the D. was vastly enlarged by the influx of these new fancies. In fact, it rose almost to a new dualism; but on the other hand, also, many mild and friendly *traits* of the heathen gods passed over into the popular conception of the D., and gave to his nature a quite new, humorous, and even merry side. As, after the introduction of Christianity, offerings were still occasionally made to the old gods, the D. shared in these honors. A horse, a he-goat, or a hound was at times sacrificed to him; and to the present day the expression has survived, "To kindle a fire for the devil"—obviously an allusion to altar-flames. Various features of the old Norse gods, especially of Loki and Donar (Thor), the gods of fire and thunder, were also transferred to him. Hence the still current phrases in Germany when thunder is heard: "The devil must be striking," and "The runaway goose is gone to the devil." (Donner, "thunder," is the word used for devil in this case.) Every power, too, which, according to the older heathen belief, was lodged in the lesser demons, giants, etc, had now its proper center in the great fiend himself, who could perform all the pranks attributed to the more grotesque creations of the Norse mythology, and work all the evil of the more malignant spirits; but, in general, these beings were rather pressed into his service than absorbed by him, or incarnated in his person.

So did this great, originally Persico-Judaic belief spread itself through all Christian lands, incorporating with itself, first, the kindred conceptions of the ancient classical world, and, ultimately, the rich and varied superstitions of our Teutonic and Scandinavian forefathers. Thus decked out in the costume of many different climes and ages, the image of evil passed into the light of the modern world. Every step forward that it now took robbed it of some potent spell that used to chill the blood and strike the heart with awful horror. Men first lost faith in the D.'s occasional incarnation; then medical science destroyed his claims to the origination of mental phenomena, which he was once supposed to have directly caused; natural science deprived him of his control over the elements; historical criticism plucked from him his borrowed feathers; while metaphysics and a deeper religious exegesis have combined, not, perhaps, to annihilate his personality or deny his influence, but certainly to realize the former under a more spiritual form, and to limit the latter by a reverential belief in the wisdom and goodness of God. See Mayer's *Historia Diaboli* (1780); Horst's *Demonomachie* (1817) and *Zauberbibliothek* (1826); and Grimm's *Deutsche Mythologie* (2d edit. 1844); also Moncreux Conway's *Demonology and Devil Lore* (1878).

At the outset of this article, it was stated that the "doctrine of the devil" had received little critical treatment from English scholars. The following appears to be the prevalent mode of regarding the subject in this country. The doctrine of the existence of a personal D., the chief of evil spirits, and directly or indirectly the author of at least all *moral* evil, is maintained by reference to the Bible, regarded as containing one revelation of truth harmonious in all its parts, and gradually developed. The Scriptures of the Old and New Testaments being thus regarded, and the supposition of conflict between the doctrines of their different books, or of error in any of them being rejected as inconsistent with a full recognition of their inspiration and divine authority, the doctrine in question is unavoidably deduced from them. It is assumed to appear in the narrative of the fall in Genesis, and the name *serpent* is again applied to the D. in the book of Revelation, where he is described as "that old serpent . . . which deceiveth the whole world" (Rev. xii. 9); he is believed to be repeatedly mentioned in the Old Testament. The hypothesis of an extra-national origination and development of the idea of the D. would, of course, be repudiated, and orthodox divines would consider it more probable that the Persians borrowed from the Jews than that the Jews borrowed from the Persians. The mention of the D. in the New Testament is held to be conclusive, not only of his existence, but of the belief in that existence (even when not expressed or hinted at) among the older Jews. The warnings and exhortations addressed to Christians are, it is also said, framed on the supposition of dangers arising from his violence, power, and subtlety. It is further argued, that the principal objections urged against the doctrine of the existence of a D. are substantially the same which present themselves to the mind as difficulties when we speculate on that which, however, is so undeniable—the existence of moral evil.

DEVIL-FISH, a name given by fishermen along the southern Atlantic and Gulf coasts of the United States to a cartilaginous fish of the ray family, *ceratopterus campipus*, Mitch. The outline of the fish is nearly an isosceles triangle, the apex at the tail, the altitude of the triangle, or length of the fish, being about half the breadth, from tip to tip, of the pectoral fins. Specimens are described as 10 ft. long, 22 ft. wide, and weighing 4 or 5 tons. A mounted specimen is in the museum of the Chicago academy of sciences. It is a small fish of the kind; 5½ ft. long, 11 ft. broad, 18 in. thick at about 2 ft. behind the mouth; and probably weighed 700 lbs. when alive. The skin is thin and rough, like that of a shark; color, slaty-black above, creamy-white beneath, but darker along the edge. The head, slightly protuberant along the base of the triangle, is retracted; mouth large and cavernous; nostrils near the angles of the mouth, in the under surface of the upper jaw; eyes protruding at the side of the head; ears, or auricular openings which serve the purpose, a little to the rear of the eyes. The mouth

is armed at either side by a flat cartilaginous protuberance, in the specimen mentioned about 12 in. long, and of the breadth and thickness of a man's hand; in life, the creature can twist this into a cone, which resembles a horn, whence the part *cera* in the generic name. These members, perhaps, act like hands in sweeping food into the mouth. There are 5 large, linear, brachial openings on each side of the under surface, in the rear of the lower jaw. The tail is very slender, like a whip-lash, four-sided, and so rough that a lash received from it would cut to the bone. The stomach of this fish contained about two bushels of partly digested algae, of a species which grows abundantly in southern waters. The evidence is against the supposition that it consumes any considerable quantity of animal food. See CEPHALOPTERA, *ante*.

In his *Travailleurs de la mer*, Victor Hugo gives a thrilling account of a nameless and horrid monster which he calls *pieuvre*, a word rendered by his translators "devil-fish." The celebrity of the narrative has attached the name to the creature there described, but which does not really exist as pictured by the novelist. The account most nearly fits the cephalopodous mollusk called the *poolpe* (see *ante*), which grows to a large size in tropical waters.

The name is also given to a fish better known as the angler, *lophius piscatorius* (see *ante*), and by ignorant fishermen to various other fishes of grotesque appearance.

**DEVIL'S ADVOCATE.** See ADVOCATUS DIABOLI, *ante*.

**DEVIL'S BRIDGE**, in Switzerland; a curious bridge over which the road to Italy crossed the Reuss. The original bridge, built in 1118, was partially destroyed by the French in 1799. It was restored, but is no longer in common use. "The Hole of Uri" is the name given to a tunnel near the bridge, through which the road passes.

**DEVIL'S DUST**, the name sarcastically given to old woolen materials manufactured into some variety of cloth. See SHODDY.

**DEVIL-WORSHIPERS**, or YEZIDEES, a sect in Koordistan and Armenia, numbering about a quarter of a million. They respect the devil, and look for him to be restored to heaven, at which time they desire his friendly services.

**DEVISE**, in English law, the conveyance of land by will. As personal property or chattels is said to be bequeathed, so lands are said to be devised. It is said, *Co. Litt.* 111 b. n. 1, that, under the Saxon and Danish rule in England, the owners of land were entitled to convey their lands by will. It is certain that so soon as feudal customs were established in this country, the testamentary power over land ceased; and from the conquest to the reign of Edward IV., this species of property could be transferred by conveyance *inter vivos* only; but during the reign of the latter monarch, a new mode of transfer began to be adopted, called a conveyance to uses (q.v.). By means of this species of conveyance, a party wishing to convey land otherwise than the common law allowed, actually conveyed the land to another person, to such uses as he should appoint. The equity courts then regarded the party in whose favor the conveyance had been made as a mere trustee, and obliged him to relinquish the land in favor of any one whom the original owner might appoint. The power of appointment thus remaining in the owner might be exercised by will. By a statute of 27 Henry VIII., this mode of passing land by will was abolished; but, five years after, by 32 Henry VIII. c. 1, followed by 35 Henry VIII. c. 5, it was enacted that all persons having estates in fee-simple should have power to devise the whole of their *socage* (q.v.) lands, and two thirds of their land holden by *knight's service* (q.v.). Finally, by 12 Charles II. c. 24, tenure by knight's service was abolished, and converted into socage; so that the power of devising land was extended to all lands except copyholds (q.v.). But to the general rule that land could not pass by will, there had always existed an exception in favor of lands, which, by the custom of the manor, had always been so conveyed; and this mode of devise by custom continued to exist even after the statute of wills of Henry VIII. For this practice there were two grounds: 1. That the power of devising lands was limited by statute to two thirds of the land held by *knight's service*, whereas devise by custom might carry the whole land. 2. In order to an effectual devise of land under the statutes of Henry VIII., it was necessary that there should be a will in writing, while a verbal or nuncupative will would carry land by custom. By 29 Charles II. c. 3, the statute of frauds (q.v.), this distinction was removed, and it was enacted that a will in writing, attested by three or four witnesses, should be necessary for conveyance of all lands. It must be observed that this power of devising lands was confined to lands belonging to the testator at the time of making his will, so that after-acquired lands would not pass by it; and also, that religious bodies and other corporations were, by the law of mortmain (q.v.), restrained from being devisees of land. Thus stood the law at the period of the recent wills act, 7 Will. IV., and 1 Vict. c. 26. By this statute, devisees of land are placed on the same footing as to execution as other wills, and will carry all landed estates belonging to the devisor at the time of his death. See WILLS, and generally on this subject, see Jarman on Wills.

In Scotland, it is usual to convey lands by deed, which has, however, precisely a similar effect to a will, so that the difference between English and Scotch wills is chiefly formal. In foreign countries the power is subject to various rules differing from those in force in England. Hence, where a person resides in one country, and is possessed of

landed property in another, questions of jurisdiction frequently arise as to the law which shall govern the power of disposal. In these cases, it is now a recognized principle that the *lex rei sitæ* is that which must prevail.—See Story's *Conflict of Laws*, p. 719, *et seq.*

**DEVIZES** (anciently *Divisæ*, *Divisis*, *De Vies*), a parliamentary and municipal borough, in the middle of Wiltshire, near the Avon and Kennet canal, 22 m. n.n.w. of Salisbury. It lies high at the mouth of Pewsey vale, between the thinly peopled tracks of Salisbury plain and the Marlborough downs. Pop. '71, 6,839. D. returns one member to parliament. It has silk-throwing mills, and manufactures of snuff and malt, and is the seat of one of the most important corn-markets of the w. of England. The corn exchange has standing-room for nearly 3,000 persons. The chancel of St. Mary's church in D. is believed to be nearly as old as the conquest. Roman household gods and coins have been found here. D. arose in a castle built by Roger, bishop of Salisbury, in the time of Henry I. This castle, of which only the walls of one of the dungeons remain, was besieged and taken by Cromwell in 1645. From the time of Henry VIII. till about 1820, D. was the seat of extensive cloth manufactures.

**DEVOIRS or CALAIS** were the customs due to the king for merchandise brought to, or carried out of, Calais while our staple (q.v.) was there.—*Concise Interpreter*. "Merchants of the west may buy merchandises, so that they find sureties to carry them to the west or to Calais."—2 Rich. II. st. 1. c. 3.

**DEVONIAN FORMATION. DEVONIAN SYSTEM** (*ante*). At the beginning of the Devonian period the dry land of North America was confined to the present territory of eastern Canada and New England. The Alleghany mountains were sketched in a series of islands and coral reefs which made a barrier between the ocean and the inland sea. There were no large rivers; the valleys of the Hudson, the Connecticut, and the St. Lawrence were merely outlined, and the Ottawa had begun its work in the azoic region between the St. Lawrence and Labrador. The Devonian period was occupied by a series of oscillations of level, the amplitude of the variations, and the consequent thicknesses of deposit being greater in the eastern part. The mediterranean of the interior opened s. into the gulf of Mexico, n. into the Arctic sea, and covered all the northern central region of the present continent with shallow lagoons, separated by low sandy areas.

According to the geologists of the New York survey, the D. F. of America is arranged thus, beginning at the top:

#### DEVONIAN AGE.

- |                            |                         |
|----------------------------|-------------------------|

|                            | { Portage epoch.        |
| 3. Hamilton period.....    | { Genesee epoch.        |
|                            | { Hamilton epoch.       |
|                            | { Marcellus epoch.      |
| 2. Corniferous period..... | { Corniferous epoch,    |
|                            | { Schoharie epoch.      |
|                            | { Cauda-galli epoch.    |
| 1. Oriskany period.....    | Oriskany red sandstone. |

1. The Oriskany sandstone extends from near Oriskany, Oneida co., N. Y., s.w. along the Appalachians into Pennsylvania, Maryland, and Virginia. It appears near Buffalo, in Canada near Waterloo, in Ohio, Indiana, southern Illinois, and Missouri. Its thickness at Oriskany is about 30 ft.; in Illinois, 250 to 300 feet. Its rocks are mostly sandstone, but there are strata of limestone in the Mississippi valley, and in the region w. and n. of Moosehead lake. Its most abundant fossils are *spirifers*, with other mollusks. There are no land-plants in the New York and western beds, but lycopods occur in the upper limestones at Gaspé.

2. The Corniferous period. The cauda-galli grit, chiefly argillaceous sandstone, is 50 or 60 ft. thick in the Helderberg mountains of eastern New York. The name comes from a characteristic fossil sea-weed of feathery form. The rocks of the Schoharie epoch are fine-grained calcareous sandstones, similar in quality and distribution to the preceding, but differing in their fossils, which are very numerous. The upper Helderberg is farther divided into the Onondaga limestone and the corniferous limestone—the latter taking its name from the presence of much imperfect flint or horn-stone (*cornu*, a horn). The corniferous limestones occur in New York, in Ohio along lake Erie, and throughout the Mississippi basin from Michigan to Kentucky, and from Ohio to Missouri. Its greatest thickness, in Michigan, is 354 feet. Its notable fossil plants are lycopods, conifers, and tree-ferns. This period was the coral-reef period of palæozoic times, and corals are found in great number and variety. The falls of the Ohio, at Louisville, are caused by such an ancient reef, and are rich in coral fossils. The remains of vertebrates first appear in the corniferous epoch. They include relics of sharks, cestraciant and hybodont; of ganoids, having the body covered with shining plates of mail, now represented by the gar-pike; and of placoderms, having the body covered with bony plates, such as are worn by the turtles—fishes which seem to have linked the ganoids with the sharks.

3. The Hamilton period includes the Marcellus shales, the Hamilton beds, and the Genesee shales. This formation extends across New York, its greatest thickness, 1500 ft., being e. of the center. It occurs southwardly to Tennessee, and westwardly to Iowa and Missouri; also in the valley of the Mackenzie, so that Meek believed that Devonian rocks are continuous from Illinois to the Arctic ocean, a distance of 2,500 miles. The Hamilton beds furnish superior flagging stones; the Genesee shales produce great quantities of petroleum, and occasionally of gas that may be used for heating and lighting. The vegetable fossils are lycopods, including lepidodendroids, sigillariids, and stigmaria, ferns, equisetæ, and conifers. The animal fossils still abound in corals and brachiopods; in this period appears the goniatites, the ancestor of the modern nautilus. Among articulates we notice a new form of trilobite, and especially the earliest insect remains, in form akin to the ephemeræ. Vertebrates are represented by fishes, like those of the corniferous period.

4. The epochs of the Chemung period are the Portage and the Chemung. The rocks of the lower, or Portage group, appear in western New York, having a thickness of 1000 ft. on the Genesee, and 1400 ft. on lake Erie. The Chemung rocks extend over the southern counties of the state, being about 1500 ft. thick near Cayuga lake. Farther s., in Pennsylvania and beyond, they become 3,000 ft. thick. Ripple-marks, mud-marks, and sun-cracked mud abound, indicating shallow seas, and lands alternately under, and out of, water. Sea-weeds and land-plants alternate.

5. The Catskill period produced shales and sandstones of various colors, chiefly red. This formation has a thickness of 2,000 to 3,000 ft. in the Catskills, and nearly 6,000 ft. in the coal regions of Pennsylvania, but thins out toward the west. It contains few fossils, and these not materially different from those of the lower periods. The Devonian age closed with an epoch of great disturbance along the eastern border. The rocks were uplifted at various angles previous to the deposition of the carboniferous strata. The rising of Maine above the sea was probably completed during this age.

**DEVONIAN SYSTEM**, the name proposed by Murchison and Sedgwick to replace the more characteristic and older term old red sandstone, because the slaty and calciferous strata in Devonshire contain a much more copious and rich fossil fauna than the red arenaceous rocks of Scotland, Wales, and Herefordshire, with which they were shown to be contemporaneous. The older descriptive name, old red sandstone, is still generally retained, and to it we refer for a description of the rocks of the system.

**DEVONPORT** (before 1824, called **PLYMOUTH DOCK**), a parliamentary and municipal borough, maritime and fortified town, and naval arsenal, in the s.w. of Devonshire, situated on Stonehouse creek, on the e. shore of the estuary of the Tamar (which is 4 m. long by half a mile broad, and called the Hamoaze), 2 m. w.n.w. of Plymouth. It stands on high ground, with ramparts defended by batteries. The s.e. and s. walls are 12 ft. high, with three gates, and externally a fosse cut 12 to 20 ft. deep in the solid rock. The streets are regular, and the footpaths of marble. D. is supplied with water from Dartmoor by a circuitous route of 30 miles. It owes its importance to the dock-yard established here by William III., and still one of the chief naval arsenals in Britain. Locally, the yard is in D., although official documents and popular phraseology frequently refer it to Plymouth. The yard comprises six building-slips, for various rates of vessels. The docks cover an area of 100 acres, and have cost an enormous sum of money. The most recent basin was completed in 1868. Rope-making, sail-making, and anchor-forging are also carried on. D. has residences for the port-admiral and governor, barracks for 2,000 men, a military hospital, telegraph establishment, victualling office, and grand parade. D. has breweries, soap-works, and an extensive trade in refitting and victualling ships. Pop. '71, 64,034, much connected with the dock-yard. D. returns two members to parliament.

**DEVONSHIRE**, a maritime county, in the s.w. peninsula of England, between the Bristol and English channels. Greatest length, 71 m.; greatest breadth, 68; average, 46; area, 2,590 sq.m., three fourths being in pasture or arable. The n. coast, 60 m. long, is mostly steep and rocky; the chief indentation being Bideford bay, 18 m. broad and 8 deep. The s. coast, 100 m. long, is also lined with cliffs, and has Tor bay, 3 by 3½ m., and Plymouth sound, 3 by 3 miles. The general surface is hilly, and the tablelands of Dartmoor in the s. of D., Exmoor in the n.e. of Devon and n.w. of Somerset, and Blackdown in the e. of D. are high, heathy, and rocky. The lower hills are grassy. The loftiest eminence is Yes Tor, in Dartmoor forest, 2,050 feet. The chief rocks are granite in Dartmoor, and Devonian, carboniferous, and Permian strata, with some Silurian strata, magnesian limestone, greensand, chalk, and trap. Copper, tin, iron, and other metals occur, with potters' and pipe clays, Bovey coal, marble, gypsum, fluor-spar, and loadstone. The rivers are very numerous, the chief being the Exe, 54 m. long.; Dart, 36; Tamar, 59; Torridge, 53; and Taw. These rivers have tidal estuaries, 5 to 11 m. long. There is an intermittent spring at Brixham. The climate is humid and equable—cool in summer, and mild in winter. The great mildness of the s. coast in winter has made it much resorted to by invalids, especially those in consumption. Here myrtles flourish in the open air, and, with a little care, the orange and lemon. From its humidity, D. is more grassy than Cornwall, and there are fine meadows along the rivers. In the s., especially in Exeter Vale, the soil is very productive.

The chief crops are grass and clovers, alternating with corn and potatoes. The fertile red loam of Exeter Vale produces wheat, barley, beans, pease, and flax. D. has much oak-wood and extensive orchards. It is famed for clotted cream and cider. The apple-trees grow on the hill-slopes and in the hedges. The chief manufactures are serges, linen, gloves, and lace; the chief exports are butter, cheese, cattle, and sheep. The red Devon breed of cattle is highly valued. Dartmoor mutton and Exmoor ponies are famous. D. has important pilchard, mackerel, dory, and salmon fisheries. The electric torpedo occurs in the estuaries. D. is divided into 33 hundreds, 470 parishes, and 17 poor-law unions. The chief towns are Exeter (the county town), Plymouth, Devonport, Tavistock, Tiverton, and Barnstaple. D. sends 17 members to parliament—6 for the county, and 11 for the above towns. Pop. in '61, 584,531; in '71, 601,374. Prior to the reform act of 1837, D. had 22 members, but by that act, and the Scottish reform act of 1868, the county gained 2 members, while the boroughs lost 7. D. has many British and Roman remains, as stone circles, dolmens, barrows, and camps. The Saxons failed to conquer D. till the 9th century. It was ravaged by the Danes in the 9th and 10th centuries, and by the Irish in the 11th century. At the reformation, 1549, there were great disturbances in Devonshire. In 1688, the prince of Orange landed at Tor bay.

**DEW.** For any assigned temperature of the atmosphere, there is a certain quantity of aqueous vapor which it is capable of holding in suspension at a given pressure. Conversely, for any assigned quantity of aqueous vapor held in suspension in the atmosphere, there is a minimum temperature at which it can remain so suspended. This minimum temperature is called the dew-point. During the daytime, especially if there has been sunshine, a good deal of aqueous vapor is taken into suspension in the atmosphere. If the temperature in the evening now falls below the dew-point, which after a hot and calm day generally takes place about sunset, the vapor which can be no longer held in suspension is deposited on the surface of the earth, sometimes to be seen visibly falling in a fine mist. This is one form of the phenomenon of dew, but there is another. The surface of the earth, and all things on it, and especially the smooth surfaces of vegetable productions, are constantly parting with their heat by radiation. If the sky is covered with clouds, the radiation sent back from the clouds nearly supplies an equivalent for the heat thus parted with; but if the sky be clear, no equivalent is supplied, and the surface of the earth and things growing on it become colder than the atmosphere. If the night also be calm, the small portion of air contiguous to any of these surfaces will become cooled below the dew-point, and its moisture deposited on the surface in the form of dew. If this chilled temperature be below 32° F., the dew becomes frozen, and is called *hoar-frost*. The above two phenomena, though both expressed in our language by the word dew, which perhaps helps to give rise to a confusion of ideas on the subject, are not necessarily expressed by the same word. For instance, in French, the first phenomenon—the falling evening-dew—is expressed by the word *serain*; while the latter—the dew seen in the morning gathered in drops by the leaves of plants, or other cool surfaces—is expressed by the word *rosée*.

The merit of the discovery of the "Theory of Dew" has been commonly ascribed to Dr. Wm. Charles Wells, who published in 1814 his *Essay on Dew*, which obtained great popularity. The merit should, however, be divided between him and several others. M. Le Roi of Montpellier, M. Pictet of Geneva, and especially prof. Alex. Wilson of Glasgow, largely contributed by experiment and induction to its formation. Its history is very interesting, and the curious reader will be well repaid by a perusal of an article on the subject by Mr. Tomlinson of King's college school, London, in the *Edinburgh New Philosophical Journal* (new series), vol. xiii. No. 1. Jan., 1861.

**DEW, THOMAS RODERICK**, 1802–46; b. Va.; graduate of William and Mary college, professor of moral science in that institution, and president, 1836. In 1838, he published an essay on *Slavery*, which is said to have put a stop to a movement then assuming considerable proportions, to proclaim emancipation in Virginia. His most important work is a *Digest of the Laws, Customs, Manners, and Institutions of Modern Nations*.

**DEWAS**, a t. of Malwa, India, 24 m. n.n.e. from Indur. It is the capital of a petty state or raj under British protection, held conjointly by two chiefs of the lineage of the Puar or Pramara Rajpoots, once very powerful, although now of fallen fortune. The military force of the state consists of 175 horse and 500 foot; the pop. is about 25,000, the revenue about £40,000.

**DEWBERRY**, *Rubus cespitosus*, a plant of the same genus with the bramble (q.v.), and very nearly allied to it, but having weaker and more prostrate roundish stems, which take root at the end, their prickles unequal and passing insensibly into hairs, the fruit consisting only of a few (1 to 5) grains, which, however, are much larger than those of the brambleberry. The name is derived from the dew-like, bluish bloom which covers the fruit. The D. is common in some parts of Britain, and in many parts of Europe and of Asia. The fruit is very sweet and agreeable, and makes an excellent wine. The D. of North America (*R. procumbens*), abundant in the forests of Canada, is a delicious fruit, much superior to the British fruit of the same name, and more tart. The plant is of very humble growth, scarcely rising above the ground.

DEWEES', WILLIAM POTTS, 1768-1841; b. Penn.; a physician. He selected obstetrics as his specialty, in which he won much reputation. He was professor of the diseases of women and children in the university of Pennsylvania. Among his publications are *System of Midwifery*; *Treatise on the Physical and Medical Treatment of Children*; *Treatise on the Diseases of Women*; and *Practice of Medicine*.

DE WETTE, WILHELM MARTIN LEBERECHE, one of the ablest theologians of modern Germany, was b. 14th Jan., 1780, at Ulla, near Weimar, and studied at the university of Jena. In 1807, he was appointed extraordinary professor of philosophy at Heidelberg; in 1809, professor of theology; and in 1810, was called to Berlin. By his popularity as a teacher, as also by his writings, De W. soon acquired a great reputation. In 1819, on account of a letter which he wrote addressed to the mother of the assassin of Kotzebue, he was deprived of his chair. Not long after, however, he was appointed professor of theology in the university of Basel, where his prelections and sermons in a short time secured him universal esteem and applause. In 1829, the grand council of Basel made him a member of the council of education, and granted him the freedom of the city. In 1849, he was elected rector of the university, but died the same year, on the 16th of June.

De W. was a man of comprehensive learning, and acute philosophic discernment. His antipathy to the shackles of dogmatic theology gave keenness and vigor to his criticism. Yet he formed no school, and followed no master, so that it is difficult to describe his position. He cannot be classed either with Paulus, Strauss, or Baur. A temperate but very decided historical rationalism, on a broad basis of moral reverence, would perhaps best express his biblical stand-point. His principal works are: *Beiträge zur Einleitung in das Alte Testament* (Contributions to an Introduction to the Old Testament), 2 vols. (Halle, 1806-7); *Commentar über die Psalmen* (Commentary on the Psalms), Heidelberg, 1811; *Lehrbuch der historisch-kritischen Einleitung in die Bibel Alten und Neuen Testaments* (Historico-Critical Introduction to the Books of the Old and New Testament), 2 vols. (Berlin, 1817-26); *Lehrbuch der Christlichen Dogmatik* (Compendium of Christian Dogmatics), 2 vols. (Berlin, 1813-16); *Christliche Sittenlehre* (Christian Ethics); *Vorlesungen über die Religion, ihr Wesen, und ihrer Erscheinungsformen* (Lectures on Religion, its Essence, and Forms of Manifestation), Berlin, 1827; *Das Wesen des Christlichen Glaubens* (The Nature of the Christian Faith), Basel, 1846; and *Exegetisches Handbuch zum Neuen Testament* (Exegetical Handbook of the New Testament). Besides these, De W. published a critical edition of the entire works of Luther.

DEWEY, CHESTER, D.D., LL.D., 1781-1857; b. Mass.; a botanist, professor of natural philosophy in Williams college; in 1850, was appointed to the chair of chemistry in the university of Rochester.

DEWEY, ORVILLE, D.D., b. Mass., 1794; graduate of Williams college, and divinity student at Andover. He preached in Boston for two years as assistant to Dr. Channing, forming a friendship which was only broken by death. In 1823, he became pastor of the Unitarian church in New Bedford, remaining there ten years. He went to New York in 1835, and while there secured the building of the "Church of the Messiah." About 1844, he quitted the pulpit and lectured in various parts of the country on "The Problem of Human Life and Destiny," and on other subjects. Among his works are *Letters on Revivals*; *Discourses on Human Nature*; *Discourses on Human Life*; *Discourses on the Nature of Religion*; *The Unitarian Belief*; etc.

DEWITT, a co. in central Illinois, intersected by the Illinois Central and the Indianapolis, Bloomington, and Western railroads; 675 sq.m.; pop. '70, 14,768. It has a level prairie and forest surface. Coal is the chief mineral product, and agriculture the main business. Co. seat, Clinton.

DEWITT, a co. in s. Texas, on the Guadalupe river; 898 sq.m.; pop. '70, 6,443—1757 colored. It has a rolling and hilly surface and fertile soil. Productions, corn, wool, butter, and cotton. Co. seat, Clinton.

DE WITT, JAX, a celebrated statesman of Holland, b. at Dort in 1625, was the son of Jacob de Witt, a vehement opponent of William II., prince of Orange. Jan inherited his father's hatred of the office of stadtholder, and the family that filled it. His education was carefully attended to, and he soon exhibited remarkable ability. He was one of the deputies sent by the states of Holland in 1652 to Zealand, for the purpose of dissuading that province from adopting an Orange policy. There his eloquence secured him universal confidence, which, however, in such troublous times could not long be retained. In the same year he was made grand pensionary. The Orange party (supported by the populace and the clergy), during the war carried on between England and Holland, was ever striving to increase the power of the young prince (afterwards William III.), who was then a mere infant; the republican, or oligarchic party, composed of the nobles and the wealthier burghesses, at the head of which was De W., sought, on the other hand, to strip the house of Orange of all power, and to abolish entirely the office of stadtholder. During William's minority, the advantage was, of course, with De W. and the republicans. In 1654, on the conclusion of the war with England, a secret article was inserted in the treaty drawn up between De W. and Cromwell, in virtue of which the house of Orange was to be deprived of all state-offices. After the restoration

of Charles II., De W. leaned more to the side of France. This tendency necessarily received an impetus from the renewal of hostilities between England and Holland in 1665. These lasted for two years; and although De W. acted with great vigor, his influence was diminished, and his party was compelled to concede a larger measure of power to the house of Orange. De W.'s prospects became still more clouded when the designs of Louis XIV. upon the Spanish Netherlands became manifest. The Orange party carried their point in the elevation of William to the family dignity of stadtholder. On the invasion of the Netherlands by Louis XIV. in 1672, the prince of Orange was appointed commander of the Dutch forces; and the first campaign proving unfortunate, the popular clamor against De W. greatly increased, who had previously resigned his office of grand pensionary. His brother, Cornelius, accused of conspiring against the life of the stadtholder, was imprisoned and tortured. De W. went to see him on his release. When they were coming out of prison, they were attacked by an infuriated crowd, and were both murdered Aug. 20, 1672. The states-general demanded an investigation, and the punishment of the murderers, but the stadtholder did not take the necessary steps. De W. was personally a man of upright character. His *Memoirs* (which were published during his lifetime) contain much important information regarding the politics of the time.

DE WITT, THOMAS, D.D., 1791-1874; b. N. Y.; graduate of the theological seminary in New Brunswick, N. J., 1812, and entered the ministry of the Reformed Dutch church. He became minister of the collegiate church in New York, 1827, and remained so all his life, a pastoral service of 47 years. He was thoroughly learned, and held many important positions, among them president of the New York historical society, and of the New York tract and mission society. He was one of the few remaining of the Reformed church clergy who could preach in the Dutch language.

DEWSBURY, a manufacturing t. and parliamentary borough in the west riding of Yorkshire, situated at the base of a hill, on the left bank of the Calder, is 32 m. s.w. of York, and 8 m. s.s.w. of Leeds. It is governed by a local board of health, possesses a chamber of commerce, and is the center of the Dewsbury union. Pop. '71, 24,764. D. is noted for its manufactures of low woolen goods—as pilots, sealskins, unions, etc.; and carpets and blankets. There are collieries and ironworks in the immediate neighborhood. Railways—London and Northwestern, and Lancashire and Yorkshire. Calder navigation connects the town with Hull and Liverpool. The parliamentary borough was formed in 1867, and includes Batley and Soothill. Pop. of p. b. '71, 54,940. D. returns one member to parliament.

Near D. is situated BATLEY, the principal manufacturing town in the kingdom for low woolen and army cloths. It is governed by a local board of health, and possesses a chamber of commerce. It is on the Manchester and Leeds line of the London and Northwestern railway. Pop. '71, 20,871.

DEXTER, HENRY, a sculptor, b. N. Y., now residing in Massachusetts, who has done some good work. In youth he was a blacksmith. Two of his works are "The Young Naturalist," and "The First Lesson."

DEXTER, HENRY MARTYN, D.D., b. Mass., 1821; a graduate of Yale, and of Andover theological seminary; Congregational pastor in Manchester, N. H., and Boston. He was one of the editors of the *Congregational Quarterly*, and in 1867 was editor-in-chief of the *Congregationalist*, Boston. Besides *Street Thoughts*, *Twelve Discourses*, and various other writings, he has published *Congregationalism*, an authentic work concerning both the principles and the usages of the churches of that order. His latest issue is *History of the Congregationalism of the last Three Hundred Years, as seen in its Literature*. This work contains an invaluable bibliography of Congregationalism, with 7,250 names of publications. As a historical scholar, industrious and keen, he occupies the first place in the department which he has chosen—pressing research to its furthest practicable point, securing accuracy in numberless details, then classifying and analyzing with a critical judgment which unfolds the vital issues.

DEXTER, SAMUEL, LL.D., 1761-1816; b. Boston; graduate of Harvard and a lawyer. He was in the state legislature, and in congress both as representative and senator. In 1800, he was appointed secretary of war, and the next year secretary of the treasury. He was a candidate for governor of Massachusetts, 1814, but was defeated by his republican opponent. He was the president of the first "temperance society" in his state.

DEXTER, TIMOTHY, 1747-1806; b. Mass.; a merchant who rose to great affluence; but memorable chiefly for his eccentricities. He assumed the title of lord Timothy Dexter. Having an itch for authorship he published *A Pickle for the Knowing Ones*. Being troubled by his printers about punctuation, he retaliated by writing a pamphlet without a comma or any other point, but at the end he put half a page of points in a mass, inviting his readers to "pepper the dish to suit themselves." He also organized his own funeral procession in the most elaborate and extensive manner.

DEXTRINE (syn. British gum, torrefied starch). When starch is carefully heated to 400° F., or until vapors arise from it, it becomes soluble in cold and hot water, and loses its gelatinous character; it also has the property, when viewed by polarized light, of turning the plane of polarization to the right; hence its name. It is often used as a

substitute for gum-arabic in the processes of calico printing, and for stiffening different goods; it is also applied to the back of postage-stamps. Its value as a substitute for gum consists in its being more flexible and less brittle when dry than that substance. Starch may be converted into dextrine by the long-continued action of dilute acids at a high temperature; also by the action of diastase (q.v.). Dextrine and starch are isomeric, both being composed of  $C_{24}H_{42}O_{20}$ ; but dextrine may be distinguished from the latter body by its pale buff color, its insolubility in alcohol, and its not being rendered blue by iodine, which gives with it a dingy purple tint.

**DEY**, a word of doubtful origin, but appropriated by the ruler of Tripoli, and also of Algiers until its conquest by the French. At one period, Tunis likewise was governed by a dey, but this title has long been supplanted by that of bey. See **BEG**.

**DHALAC**, an island in the Red sea, off the coast of Abyssinia, in lat.  $15^{\circ} 46'$  n., long.  $40^{\circ} 6'$  east. It is 30 m. long, 15 m. in average breadth, and 120 m. in circumference. It is composed of coral rock, and its surface in general is flat and sandy. Doobelloo, a village on the e. side, trades with Lohela and Ghizan, ports on the Arabian coast, exchanging fish, sharks, fins, turtle, and pearls, for millet and dates. The groups of islands in the vicinity of D. are called the Dhalac archipelago. The inhabitants are good sailors and skillful fishermen.

**DHAMEE**, a hill-state of India, of about 25 sq.m., on the left bank of the Sutlej, in about lat.  $31^{\circ} 12'$  n., and long.  $77^{\circ} 8'$  east. It is merely a collection of mountains and valleys. The general elevation probably exceeds 4,000 ft., and even the margin of the river is 2,283 ft. above the level of the sea. D. contains 5,500 inhabitants, and yields a revenue of about 8,000 rupees a year, of which 360 rupees are paid as tribute to the British government.

**DHAR**, a t. situated on the table-land of Malwa, in central India, stands in lat.  $22^{\circ} 35'$  n., and long.  $75^{\circ} 20'$  e., at an elevation of 1908 ft. above the sea. It is said to have at one time consisted of 20,000 houses, implying a pop. of about 100,000, and though very greatly decayed, it yet retains many traces of by-gone magnificence—two large mosques of red stone, ten water-tanks of various sizes, and a fort defended by many considerable towers. It is the capital of a protected state of the same name, having an area of 2,061 sq.m., with 125,000 inhabitants.

**DHARWAB**, a t. in the province of Bombay, close to the frontier of Madras, stands in lat.  $15^{\circ} 28'$  n., and long.  $75^{\circ} 4'$  east. It has government schools for Mahrattas and Canarese, besides schools established by the natives themselves. D. is the center of a cotton district. Pop. '72, 27,136.

**DHARWAR**, the district of which the t. before mentioned is the capital, extends in n. lat. from  $14^{\circ} 16'$  to  $15^{\circ} 50'$ , and in e. long. from  $74^{\circ} 50'$  to  $76^{\circ}$ , containing 4,565 sq.m., and (1872) 988,037 inhabitants. Its drainage is divided between the Arabian sea and the bay of Bengal, passing to the latter by the Tumbudra, a feeder of the Kistnah or Krishna, and to the former by the Kali Nadi, through a deep valley of the western Ghats. The most interesting feature of the country is its suitability for the growth of American cotton. In 1842, after several previous failures, the New Orleans staple was cultivated with success to the extent of 25 acres; and within five years, the breadth of land thus sown had increased a thousand-fold. In connection with this enterprise, a good road has been constructed to Coompta, on the Arabian sea, where the cotton is shipped for Bombay. It is hence commonly called "Coompta cotton." The prevalent language is Canarese, and there are a number of vernacular schools in the district.

**DHOB**. See **CYNODON**.

**DHOLE**, *Canis scylax*, an Indian species of dog, existing in a wild state in the western Ghats and some other mountainous districts. It is in size between a wolf and a jackal, with rather long legs, sharp muzzle, wide and pointed ears, straight and not bushy tail, light-bay color, fierce keen eyes, and great courage. The name D. is extended to some other very similar species or varieties, natives of Ceylon, Nepal, and other parts of the east, to which the common name *red dogs* has been sometimes applied, and for which col. Hamilton Smith has proposed the sub-generic name *chryseus*. They seem not incapable of domestication, but whether any of the domesticated dogs are derived from them is wholly uncertain. There is no reason to think that any of them are the wild offspring of once domestic races. They all want the second tubercular tooth in the lower jaw, have oblique eyes, and the soles of the feet hairy. They hunt in packs. They are all inhabitants of the deepest recesses of wild mountain-forests. A remarkable characteristic of the dholes is their hostility to the feline races, the weaker and the young of which they attack and destroy. To this is ascribed the alarm which the tiger exhibits at the sight even of a domestic dog; and "we may surmise," says col. H. Smith, "that the species of *chryseus* are the instruments nature has appointed to keep down the superabundant increase of the great *felina* of the wilderness."

**DHOLKA**, a t. of India, in the British district of Ahmedabad, presidency of Bombay. It is surrounded by a mud wall 4 m. in circuit. Pop. '71, 20,854.

**DHOLPORE**, a t. of Hindustan, on the left or n.w. bank of the Chumbul, is in lat.  $26^{\circ} 41'$  n., and long.  $77^{\circ} 58'$  e., being 34 m. to the s. of Agra, and 37 to the n. of

Gwalior. Here are some elaborately wrought mosques and mausoleums of freestone. Of the former, one is said to have been built by Shah Jehan, the founder of the modern Delhi, in 1634; and of the other edifices, some are of still earlier date. D. is the capital of a protected state stretching along the left bank of the Chumbul, containing 900 sq. m., and 200,000 inhabitants.

**DHOORCATEE'**, a protected state in Hindustan, of not more than 5 sq. m., is in lat.  $31^{\circ} 8' N.$ , and long.  $77^{\circ} 40' E.$ , lying in the basin of the Jumna towards that of the Sutlej. Small as it is, it is worthy of notice as containing the peak of Toongroo, which, at an elevation of 10,102 ft. above the sea, forms one of the stations of the large series of triangles in the trigonometrical survey of the Himalayas.

**DHUBBOOE'**, a decayed t. in Guzerat, belonging to the Guicowar, in lat.  $22^{\circ} 8' N.$ , and long.  $73^{\circ} 25' E.$ , lies 78 m. to the n.e. of Surat, and 225 to the n. of Bombay. It presents many memorials of ancient grandeur—such as a rampart of 2 m. in circuit, backed inwardly by a handsome colonnade; a magnificent tank, bordered by a grand flight of stairs and numerous Brahmanical temples—the whole richly adorned with curious sculptures. But a still more remarkable circumstance is, that, in a purely alluvial neighborhood, where even a pebble is unknown, all these structures are of hewn stone. The population, which is inconsiderable in number, shares the place with swarms of monkeys.

**DHUMTOUR'**, or **DUMTAUR**, a valley of the Punjab, stretches in n. lat. from  $34^{\circ}$  to  $34^{\circ} 10'$ , and in e. long. from  $72^{\circ} 55'$  to  $73^{\circ} 15'$ . Here a traveler from the n. first finds the peculiar vegetation of Hindustan. While behind him are luxuriant forests of oak, plane, walnut, and pine, the sugar-cane grows before him in such abundance as to form a principal article of fodder for cattle. The population is distributed into villages, each defended by a small fort against neighboring marauders. The chief town, of the same name, is 16 m. to the e. of the Indus, on the route between Attock and Cashmere.

**DHUNCHEE**, or **DIAXCHI**, *Sesbania aculeata*, a plant of the natural order *leguminosae*, sub-order *papilionaceae*, of a genus having an elongated many-seeded pod, alternately swollen and contracted, as if it contained a string of beads. The D. is an annual herbaceous plant, much cultivated in Bengal upon account of its fiber; it has an erect, sparingly branched stem, 6 to 10 ft. high. It is a plant of rapid growth, and succeeds best in low and wet soils. Its fiber is coarser than hemp, unless when it is cut at a very early period of its growth, is durable in water, but contracts considerably when wetted. It is steeped and prepared very much like sunn (q.v.).

**DHWALAGRI**, once supposed to be the highest peak of the Himalayas, but now ascertained to be at most only the third in point of altitude, is stated at 26,826 ft. above the sea. Its lat. and long. are  $28^{\circ} 42' N.$ , and  $82^{\circ} 32' E.$  The mountain is within the limits of Nepal.

**DIABETES** (Gr. literally a syphon, from *diabainō*, I go or flow through), a disorder of the general system, of which the principal symptom is a very much increased flow of urine. Diabetes is of two distinct kinds: the one, *diabetes insipidus*, is a mere exaggeration of the water-excreting function of the kidneys, accompanied by extreme thirst, and hence called *polydipsia* (Gr. excess of thirst) by some authorities; the other is a more complex disorder of the assimilation, consequent on the formation first, and the excretion by the kidneys afterwards, of an enormous excess of animal sugar (see **GRAPE-SUGAR**), the sugar being found in excess, not only in the renal excretion, but in the blood, and in nearly all the secretions which have been examined. The pathology of this disease, called *diabetes mellitus* (Lat. *mell*, honey), is very obscure, notwithstanding the numerous recent physiological researches which tend to throw light on the development of sugar in the animal organism, and which must undoubtedly be regarded as bearing on the solution of the problems connected with this disease. Unhappily, the cure of it is still entirely unknown, except in so far as it may be controlled or retarded by good management of the diet, drink, and clothing. All diabetics are subject to progressive emaciation, and they often become subject to true tubercular consumption (q.v.), or other chronic disease of the lungs; it is chiefly in warding off this termination that the medical art can be of service, as well as in relieving the symptoms as they occur. The first fact observed in cases of diabetes is usually the increased flow of urine, when it becomes so great as to amount to a practical inconvenience; and also a considerable increase of the appetite, and an unquenchable thirst, which rarely fail to accompany the disease from the beginning, but often do not attract attention, or at least suggest the idea of anything wrong, till an advanced stage of the disorder. When the patient demands medical assistance, he is usually somewhat thin; the pulse is quiet, the skin cool, the heat of the surface, indeed, habitually rather low and easily depressed. There is often a complete absence of perspiration, which gives a peculiar feeling of harshness to the surface, especially of the palms of the hands. With these symptoms, the first approaches of pulmonary disease may concur. In the very last stages, there is sometimes dropsy of the feet; and the urine may be natural in quantity, or even diminished. For the other characters of diabetic urine, see **URINE**. The cure consists in removing from the diet, as far as possible, consistently with comfort and due nourishment, everything which easily turns to the formation of animal sugar in the system,

especially all excess of farinaceous food. The complete suppression of sugar-forming food, however, as recommended long ago by Rollo, has not been found possible in practice in the majority of cases. Bread composed of gluten of wheat without starch, or bran-cakes baked with eggs, have been strongly recommended; and in most of the great capitals, as London and Paris, bakers may be found who regularly furnish bread suitable for this unfortunate class of sufferers; indeed any intelligent baker who will take the trouble, may, under medical direction, be got to manufacture such bread when required; or it may be ordered in the form of cakes and biscuits, in quantities at a time, from London houses. Dr. Camplin, himself a diabetic patient, has minutely studied the diet and regimen required, and published a little book, which we have no hesitation in recommending to all concerned, *On Diabetes, and its Successful Treatment*, in which full directions will be found for the manufacture of palatable and useful diabetic bread. The "success" alluded to, however, is simply keeping the disease at bay by constant watchfulness. Medicines proper should be used only under the advice of the physician. There is no specific, and the unguarded use of strong remedies is to be condemned. Flannel should be worn next the skin, and the languid function of the cutaneous perspiration aided by the warm bath. The Turkish bath might possibly prove useful in this disorder, and could hardly do harm if carefully employed; but we have not heard, as yet, of any actual experiments in this direction for the cure of diabetes.

**DIABETIC SUGAR** is a variety of sugar found in the blood and secretions of the higher animals, especially when afflicted with the disease called diabetes. It is a variety of grape-sugar or glucose. See GRAPE-SUGAR.

**DIABLERETS**, a remarkable mountain of the Bernese Alps, Switzerland, situated between the cantons of Bern and Valais, in lat. about  $46^{\circ} 18'$  n., and long.  $7^{\circ} 15'$  e., with an elevation of 10,670 ft. above the sea. The D. is composed of limestone strata, the lower beds of which are so soft and shaly, that they are easily disintegrated by the infiltration of water given off from the glaciers on the n.e. The consequence is that, the foundation being worn away, the peaks tumble over into the valley, occasioning the most terrible catastrophes. Three peaks have already fallen in this way, and the two that yet remain threatened to follow sooner or later. In the fall in 1714, 15 people, 100 head of cattle, and 55 chalets were destroyed; and the result would have been much more appalling, had not premonitory noises given the inhabitants timely warning to escape. In 1749, the fall of another peak arrested the course of the Liserne, which thereafter formed two small lakes known as Derborenze.

**DIACAUSTIC**. See CAUSTIC.

**DIA'CHYLON** (Gr. literally, from juices—i.e., vegetable juices, a deceptive etymology, as the plaster has really no such composition), the common healing or adhesive plaster, made by combining litharge, or the red oxide of lead, with olive oil, so as to form a kind of soap. The preparation of this plaster is now entirely taken out of the hands of druggists, it being prepared on the great scale by machinery.

**DIADEL'PHIA**, the 17th class of the Linnean system, comprising plants of which the filaments are united in two sets of brotherhoods.

**DI'ADEM** was the name given to the fillet of silk, woolen, or linen which served as the distinguishing ornament of kings. It was generally narrow, being only a little broader on the forehead. The diadem of the Egyptian goddesses and kings bore the symbol of the sacred serpent. The diadem of Bacchus, as it appears in ancient sculptures, was a plaited band going round the forehead and temples, and tied behind, with the ends hanging down. Among the Persians, the D. was bound round the tiara or turban, and was of a blue color, worked with white. The early Roman emperors refrained from using this ornament, in order not to call up recollections of the hated kingly office. Diocletian was the first to introduce it again, and Constantine the great added new ornaments to it. After his time, it was adorned with a single or double row of pearls and precious stones. Queens are also seen on coins ornamented with the D., with the addition of a veil. It was finally superseded by the crown (q.v.).

**DIE'RESIS** (Gr. *diairo*, I divide), a term used in grammar to signify the resolution of a diphthong, or of a contracted syllable, into two syllables; as Lat. *auræ* into *aurai*. The name is also given to the mark ' placed above a vowel letter, to indicate that it is to be independently pronounced, and not in conjunction with a preceding vowel; as in the above example, or in the word *aërial*.

**DIAGNOSIS** (Gr. *dia*, through, and *gnosis*, knowledge), the through-knowledge or thorough knowledge of a disease, embracing its points of distinction from other diseases, its symptoms, their relation to one another, and to the state of the different organs and functions of the body, in so far as this can be appreciated during life. D. is usually spoken of in contrast with prognosis, which implies the judgment framed by the physician as to the issues of disease; and also with prophylaxis (*pro*, from, and *phylaxis*, protection), which refers to the warding off disease, when supposed to be impending. D. includes the study of all the vital phenomena of diseases, and also of their appearances after death, in so far as this can aid their discovery during the life of the patient. It is

usual to speak of rational or physiological D., or D. by symptoms—i.e., functional changes; and of physical D., or D. by signs—i.e., objective phenomena appreciable by the senses of the observer. The latter method of D. has been much enlarged in scope, and increased in importance of late years by the modern discoveries in auscultation (q.v.) and percussion (q.v.), and also by the great advances made in physiological chemistry, and by the use of the microscope.

**DIAGOMETER**, a kind of electroscope, in which a dry pile is employed to measure the amount of electricity transmitted by different bodies, or determine their conducting power. Used to detect foreign mixture in olive oil.

**DIAGONAL**, in plane geometry, is a straight line joining any two angles not adjacent, of a rectilinear figure. A line drawn between two adjacent angles would coincide with the boundary-line. A triangle has no diagonal, because any two of its angles are adjacent; a four-sided figure has two diagonals; a five-sided, five; a six-sided, nine; etc. The number of possible diagonals in any figure is found by taking three from the number of sides, multiplying the remainder by the number of sides, and taking half the product. Thus, in the six-sided figure, the process is  $\frac{3 \times 6}{2} = 9$ . If the diagonals

must be so drawn as not to intersect, their number is always three less than the number of sides. It makes no difference whether they all proceed from one angle or not. A diagonal in a solid bounded by planes, is a line joining any two solid angles so situated that the line does not coincide with any line on the surface. To find the number of such diagonals in a given solid: Multiply the number of solid angles by the same number diminished by one, and from half this product subtract the number of edges on the figure, and also the sum of the number of diagonals in all the faces. Thus, the cube

gives  $\frac{8 \times 7}{2} - 12 - 6 \times 2 = 4$  diagonals.

**DIAGONAL SCALE**, a system of lines by means of which hundredths of units may be laid down or measured with compasses. When the numbers representing the lengths of the sides of any figure would give lines of an inconvenient size taken from the scale, the numbers may be all multiplied or all divided by such a number as will adapt the lengths of the lines to the required dimensions of the figure.

**DIAGORAS**, a Greek poet and philosopher, was b. in Melos, an island of the Cyclades. He flourished in the 5th c. B.C., but beyond his reputation for atheism, nothing very positive is known regarding his career. He is said to have been a disciple of Democritus of Abdera, and to have resided during the more important part of his life in Athens. He is alluded to by Aristophanes in the *Clouds* (424 B.C.); and from an epithet applied there to Socrates, it is highly probable that that great philosopher had been a pupil of D., or at least held similar opinions. This will perhaps explain to us the accusation brought against him of atheism. In all likelihood, D. was no atheist, but simply a *disbeliever in polytheism*; and the anecdotes related of him, such as his once throwing, when ill-off for fuel, a wooden image of Hercules into the fire, to cook his dinner, serve to confirm such a supposition. He seems to have been witty and fearless, and probably treated the rude superstitions of the common-place Athenians with dashing contempt. In this way he may have become specially notorious, and so fixed himself in the Greek mind as the *representative* atheist. D. was banished from Athens professedly on account of his impiety, but really on account of his politics. He went first to Pallene, and afterwards to Corinth, where he died. He wrote lyrics of various kinds, and a philosophical work entitled *Phrygion Logoi*. Personally, he was a man of untainted character, and discharged his duties as a citizen in an earnest and exemplary manner.

**DIAGRAM**, a figure so drawn that its geometrical relations may illustrate the relations between other quantities. The area of a rectangle is the product of its length and breadth; the diagram of the rectangle becomes the visible symbol, corresponding to the equation  $a = bl$ ; by analogy, the rectangle may be used to symbolize any quantity which is the product of two factors. Similarly, a parallelopiped may symbolize any quantity which is the product of 3 factors; e.g., interest, which is the product of principal, rate, and time,  $i = p.r.t.$ , may be symbolized by a diagram in which principal is figured by length, time by breadth, and rate by height, the total volume representing the interest.

The purpose of ordinary mathematical diagrams is simply illustration, and it is therefore necessary only that the ideas be clearly presented, accuracy of drawing being unimportant. Other diagrams, as some drawn by engineers and architects, are intended to furnish magnitudes or distances by actual measurement, and their execution cannot be too careful. Other diagrams, like those showing electric connections, require only a proper showing of the parts and the methods of uniting them. A profile diagram shows such an outline as would be formed, for example, if a hill were cut through by a vertical plane, and the material on one side of the plane were removed. Evidently a succession of such profiles might be laid upon the same sheet of paper, the lines being distinctively drawn, and the whole would serve to compare several vertical profiles of the same mass. It is not necessary that vertical and horizontal measurements should con-

form to the same scale, provided that each series of measurements is consistent with itself. Geographical profiles, which include upon a single sheet the outlines of entire continents or ocean-beds, have usually the vertical measurements on a scale several times greater than that used for horizontal distances; otherwise the diagram would be made inconveniently long, or the heights would be inconspicuously small. Yet the impression left by such a diagram is often mischievous, especially upon the illiterate. A topographer's contour map exhibits a series of curves, such as would be formed if a series of horizontal sections were made, and the outlines carefully laid down upon paper. The drawing may be understood to show the horizontal projections of the contour lines upon a surface parallel to the system. In the representations of parts of machinery, particularly those designed to guide workmen in construction, several connected views of the same object are required, each view giving some information which the others cannot furnish. Suppose three planes perpendicular to each other, like the bottom, one side, and one end of a rectangular box, and let an object, as a hexagonal nut, be placed within the triedral angle thus formed. Looking from the front, we see one image of the nut projected against the back of the box; from the side, a different image is seen against the end of the box; from above, a third form appears against the bottom of the box; while from one or other of these figures all the measurements of the nut may be obtained. If now the end of the box were swung outward into the plane of the back of the box, and then both together were laid back into the plane of the bottom, we should have the three co-existent drawings in one plane, and they may be transferred to, or be constructed on, one sheet of paper. In many cases the same points will find representation upon each of the three diagrams, and the fact may be indicated by using the same letter for a point wherever it occurs; while the eye may be led from one position of it to another by lines, conventionally drawn, as fine, or dotted, or broken, to show that they are merely guides and not parts of the diagram.

Many devices have been invented by which diagrams illustrating natural phenomena may be automatically described. Let us suppose that a spring dynamometer is placed where it may receive the draft of a horse when moving a carriage. Let the movement of the spring be shown by an index whose motion is back and forth along a line in the direction of the draft. Fix a pencil to the index, and let its point rest upon a sheet of paper on a plane or a cylinder which moves at a uniform velocity in a direction perpendicular to the motion of the index. The combined movements of the pencil and the paper beneath it will trace a line more or less irregular. If the force of draft were unvaried, the pencil would remain at a constant distance from the edge of the paper, and the trace would be parallel to the edge. If the paper does not move and the pencil varies, the line will be perpendicular to the edge. If both move, and the pencil be obedient to a diminishing force, the trace will be oblique, approaching one edge; while if the force increase, the oblique trace will diverge from the same edge. Such mechanism is often arranged for instruments which indicate meteorological changes, as the force and direction of winds; or the pulsation of the arteries, as in the sphygmograph; or the movements of a clock, combined with the observations of an astronomer, as in the chronograph; applicable also to many physical problems. An application of the same principle has great importance in the indicator diagram, by which the pressure of the steam in the steam-engine and the work done by each stroke of the piston, becomes a matter of record for investigation. The paper moves with the movement of the piston, both in its excursion and return; the pencil moves at right angles to the direction of the motion of the paper, under the influence of the steam-pressure; and the diagram drawn shows for each instant of the stroke the volume and pressure of the steam, while the total area of the diagram indicates the amount of work done.

**DIAL, THE**, a magazine founded, 1840, in Boston, to represent what was then known as the "transcendental" school of thought in philosophy and religion. It was continued only 4 years, first under the editorship of Margaret Fuller, assisted by George Ripley and Ralph Waldo Emerson; afterwards under Ripley's editorship. It was distinguished for the boldness and ability with which it announced and defended theories of men and society then quite novel. Many able writers contributed to its pages.

**DIAL AND DIALING.** A *sun-dial* is an instrument for measuring time by means of the motion of the sun's shadow cast by a stile erected on its surface. It is an instrument of very great antiquity, the earliest mention of it being in Isaiah xxxviii. 8; and before clocks and watches became common, it was in general use as a time-keeper. The art of constructing dials to suit any place and situation, was then an important branch of mathematical study; now the subject is more an object of curiosity than utility.

A dial consists of two parts—the *stile* or *gnomon*, usually the edge of a plate of metal, always made parallel to the earth's axis, and pointing towards the north pole; and the *dial-plane*, which may be of any hard substance, and on which are marked the directions of the shadow for the several hours of the day, their halves, quarters, etc. Dials receive various names, according, mostly, to the positions which they are constructed to occupy. When the dial-plane is on the plane of the horizon, the dial is called a horizontal dial; when perpendicular to that plane, a vertical dial. An equinoctial dial is one whose plane is parallel to the equinoctial plane. Besides these names,

there are others, such as the s. dial, n. dial, e. dial, w. dial, polar dial, declining dial, of which it is useless to write at length. These names all depend on the position of the dial-plane. The cylindrical dial is a dial drawn on the curved surface of a cylinder. The ring dial is an ingenious small portable dial, but rather a curious toy than a philosophical instrument.

A *night or nocturnal dial* is an instrument for showing the hour of the night by the shadow of the moon or stars. Moon-dials may be constructed relative to the moon's motion; or the hour may be found by the moon's shadow on a sun-dial by the following rule: Observe the hour pointed out by the moon's shadow; find the days of the moon's age in the calendar, and take three fourths of that number for the hours to be added to the time shown by the shadow to give the hour of the night.

*Dialing*.—The *stile* of a dial being parallel to the earth's axis, those familiar with spherical trigonometry will readily see that the problem of constructing a dial resolves itself into that of ascertaining where the hour-lines cut a given circle, with a view to the graduation of the dial-plane. We do not here presume the reader to be acquainted with spherical trigonometry, and accordingly proceed to illustrate the principles of dialing in a popular manner, taking our illustrations from Ferguson's *Lectures* (4th ed., 1772, lecture 10), which should be referred to for fuller information. Suppose a hollow and transparent sphere, as of glass, to represent the earth; and suppose its equator divided into 24 equal parts by the meridians, one of them passing through a given place, say London (see *HORIZON*). If the hour of twelve be marked at the equator, both on the latter meridian and that opposite it, and all the rest of the hours in order on the other meridians, those meridians will be the hour-circles of London, because, as the sun appears to move round the earth in 24 hours, he will pass from one meridian to another in one hour. Then, if the sphere has an opaque axis, terminating in the poles, the shadow of this axis would fall, in the course of the day, on every particular meridian and hour, as the sun came to the plane of the opposite meridian, and would thus show the time at London, and at all other places on the same meridian as London. If the sphere were cut through the middle by a plane in the rational horizon of London, and if straight lines were drawn from the center of the plane to the points where its circumference is cut by the hour-circles of the sphere, those lines would be the hour-lines of a horizontal dial for London; for the shadow of the axis would fall upon each particular hour-line of the dial, when it fell upon the like hour-circle of the sphere. Similarly, if we suppose the sphere cut by *any* other plane facing the meridian, the hour-circles of the sphere will cut the edge of the plane in those points to which the hour-lines must be drawn straight from the center; and the axis of the sphere will cast a shadow on these lines at the respective hours. The like will hold of any plane, whether it face the meridian or not, provided it do not coincide with it, or do not coincide with a plane through the poles, and perpendicular to the plane of the equator. In the latter case, the axis would have no elevation above the plane of the dial; in the former, the shadow would not move circularly.

The *universal dialling cylinder*, an invention of Ferguson's, is a glass cylindrical tube, closed at both ends with brass plates, on the centers of which a wire axis is fixed. The tube is either fixed to a horizontal board at an angle equal to the latitude of the place, or moves on a joint, so that it may be elevated till its axis is parallel to the earth's at any latitude. The 24 hour-lines are drawn on the outside of the glass, equidistant from one another, and parallel to the axis. The XII on the upper side of the cylinder stands for midnight; the XII next the board, for noon. When the axis is adjusted for the latitude, and the board leveled, with both XII, noon and midnight, in the plane of the meridian, and the end towards the n., the axis, when the sun shines, will serve as stile, and cast a shadow on the hour of the day among the parallel hour-lines. As the plate at the upper extremity of the cylinder is perpendicular to its axis and parallel to the equator, right lines drawn from the center to the extremities of the parallels will be the hour-lines of an equinoctial dial, and the axis will be the stile. A horizontal plate, if put into the tube, with lines drawn from the center to the several parallels cutting its edge, will be a horizontal dial for the given latitude; and similarly a vertical plate fronting the meridian, and touching the tube with its edge, with lines drawn from its center to the parallels, will be a vertical s. dial, the axis of the instrument in both cases serving for the stile; and similarly for any other plate placed in the cylinder. If, instead of being of glass, the cylinder were of wood, any of these dials might be obtained from it by simply cutting it in the planes of the plates, and drawing the lines on the surface of the section.

**DIALECT.** In speaking of a people having essentially all one language, but living extended over an extensive territory, the name of dialects is given to those varieties or peculiar forms which that language assumes among the various tribes or other local divisions of the people. It is clear that the wider the separation comes to be between the several tribes, and the more they differ in mode of life and other circumstances, the more marked will the differences of D. become. Also, when a particular tribe of this people increases in numbers, and also extends its territory, the same process is repeated, and its D. becomes broken into a number of sub-dialects. The principal check to this tendency to seemingly endless subdivision of language, is furnished by an increasing

degree of common culture and civilization. Where this is wanting, as in Africa and among the native populations of America, the subdivision is practically endless.

Another element is introduced into the problem by the fact, that the civilization of some tribes develops itself more richly and ripens earlier than that of others, while some even undergo decline; this must occasion corresponding differences of dialect. Further, one dialect may become dominant over one or more of the others, through various influences, the chief of which is the power of poetry, especially if favored by external relations. Finally, if to superior manifestations of oratory and poetry in any dialect, the conservative aid of writing be added, there is created a written language, which passes current among other tribes to the same extent that the literature of which it is the vehicle finds favor. It is not always the dialect most perfect in itself, nor yet that of the most powerful tribe or division of a people, that comes to be the written language. Accidental circumstances have, in many cases, decided the rivalry. The Bible happened to be translated by a high German, Luther, into his native dialect; other works on the then all-engrossing subject of religion followed in the same dialect; happily, too, the art of printing had just attained the perfection necessary to give these productions general circulation. It was this concurrence of circumstances that decided that high German should in future be the spiritual bond among the wide-spread German people. For there were other dialects whose claims to the distinction were at that time equal, if not higher. See also ENGLISH LANGUAGE.

When a dialect has thus become the vehicle of written communication, and of the higher kinds of oral address, its character and position become changed; and it stands henceforth in a sort of antagonism to the other dialects, and even to that out of which itself sprung. For written language is chiefly employed in the higher departments of human thought and activity. The intellectual and moral elements, therefore, predominate in it over the sensible; and what it gains in dignity, precision, and pliancy, it loses in richness of inflection, in friendly familiarity and naturalness. In conflict with this standard speech, the dialects must go to the wall. They live for a considerable time, it is true, even in the mouth of the educated classes, becoming, however, gradually more and more confined to the most necessary and familiar forms of intercourse, and losing their characteristics in the stream of the written language. They thus become, after a time, the exclusive possession of the lower orders, in which position they preserve many relics of old grammatical forms long after these have disappeared in the language of literature, but without the power of advancing or of being enriched by the products of deep thinking; and though they may abound in single expressions of great beauty and delicacy, the general character comes to be low and coarse. But so long as a language lives, the literary standard and the dialects never cease to act and react on one another.

The chief points of difference between the dialects of a language and the standard fall under four heads. The first consists of differences in the elementary sounds or letters, each dialect having a tendency to substitute some one or more vowels or consonants for others. Thus, the standard English *bold*, is in Ireland *bawld*; in Scotland, *bawld*; *what*, where the *h* is nearly evanescent, becomes, in a Scotsman's mouth, or rather throat, *cheat*, and in Aberdeenshire Scotch, *fut*—*f* in this sub-dialect being regularly substituted for *wh*, or rather *hw*. 2. Each dialect has peculiarities of grammar: In many parts of England and in Scotland, the plural of *eye* is not *eyes*, but *eyen*, or *eyu*, like *ozen*. The habitual use of *be* where the standard grammar prescribes *am*, *is*, *are*, etc., is prevalent in large districts of England. Of this kind is the use of the strong conjugation for the weak, or *vice versa*; as *loup*, *lup*, *luppen*, for *leap*, *leaped*, *leaped*. 3. Peculiarities of vocabulary: These individual words current in one or more districts, but unknown to the standard vocabulary, are properly *provincialisms*. They are generally genuine words of an older stage of the language, that have survived longer in some localities than in others. Some provincialisms, as *bearn* or *bairn*, for child, *marrow* for fellow or match, to *greet* for to weep, are common to Scotland and the n. of England. Others are more local, as to *cleam*, for to fasten or cement; *heppen*, a Yorkshire term for pretty near; *therippa*, in Cheshire, to cudgel. The exclusion of such words from the standard language is often accidental, and many of them might be and are with advantage resumed; ex., *marrow*, *gloaming*, etc. 4. Peculiarities of intonation: This is sometimes, though with little propriety, called accent, which means strictly the stress laid upon a particular syllable of a word. There are no doubt local peculiarities of this kind too. The tendency of standard English, especially the more recent, is to throw the accent toward the beginning of the word; in Scotland, the tendency lingers to say *enry* for *entry*. But peculiarities of intonation lie in the different ways in which the *pitch* of the voice is managed—in the musical accompaniment of articulation. Differences in this respect give rise to the monotonous drawl of one district, the angry querulous tone of another, the sing-song of a third, etc.

So long as dialectic varieties of language were looked upon indiscriminately as corruptions and barbarities, they were only noticed by scholars that they might be avoided. A more rational philology, without trenching upon the rules of good writing, considers them as essential parts of the speech of a people, and a knowledge of them as necessary to any thorough investigation of the genius of that speech.

It is obvious that *dialect* is entirely a *relative* term, and that what we call by that

name in one connection, we may call a language in another connection. Thus, Greek and Latin may be called sister-dialects of that primitive language from which it is held that they, as well as the other members of the Indo-European family, branched off. See ARYAN LANGUAGES. Speaking of Greek by itself, however, it is a language, and Ionic, Doric, Attic, etc., are dialects of it. The same holds good with the others. In practice, however nearly related the speech of two peoples may be, we do not apply the term dialects, unless the peoples are mutually intelligible and have a common literary standard. Intelligibility does not go for much, but political relations enter more or less into the notion. Thus, Scotch is sometimes spoken of as a distinct language from English; and yet in no part of Scotland is the common speech so unintelligible to an Englishman as is that of Somerset, which is always a "dialect." This arises from Scotland being thought of as a separate country, which it once was; and its speech as the vehicle of a peculiar literature. See AMERICANISMS.—Dialect is not to be confounded with artificialities, such as the jargon of thieves.

**DIALECTIC** is a Greek word which signified originally "the art of conversation," but came to have a technical signification in the language of philosophy. At first, it implied a regular and scientific method of treating general conceptions or general terms—a sort of anatomy of names, and through them of the things denoted. In the Socratic philosophy, and more especially in that of Plato, dialectic was thus the method of the highest and deepest kind of speculation. Aristotle gave another signification to the word. According to him, a scientific proof or deduction is different from a dialectic proof, which is only a probable deduction. After this, dialectic came round to imply a sort of word-fence, the art of so using the forms of reasoning as to confound your opponent, and make fallacies pass for truth. Dialectic is sometimes used as synonymous with logic. Logic, however, which originated with Aristotle, is properly the science of the forms of thinking; it is less directly concerned with words than dialectic, which in this view becomes a subordinate province of logic—the art of disputation. Dialectic, in fact, is little heard of where philosophy is positive and experimental; it is chiefly used with regard to the more ideal and *a priori* speculations of such philosophers as Kant, Hegel, Schelling, etc.

**DIALLAGE**, or SCHILLER-SPAR, a mineral nearly allied to augite (q.v.), and by some regarded as a variety of it. Its chemical composition is essentially the same. It is seldom found very perfectly crystallized, but usually massive, granular, or disseminated. It has generally a metallic and pearly or silky luster. A very beautiful bright green D. (smaragdite), found in Switzerland, Italy, Corsica, India, Labrador, etc., is prized for ornamental purposes; in Corsica, it occurs disseminated in a feldspar (*Labradorite* or *Suassurite*), which, when cut and polished, appears spotted with it, and is of great beauty, is made into boxes, vases, etc., is much valued, and is known by the names *gabbro* and *verde di Corsica duro*. A variety of D., usually yellowish or brownish, is sometimes called *bronzite*.

**DIALOGUE**, a conversation between two or more persons, implying, however, greater unity of subject and formality than an ordinary conversation. The ancient Greek philosophers were fond of this way of conducting their investigations and conveying their instructions. The Socratic dialogue is a conversation in the form of question and answer, so contrived that the person questioned is led himself to originate those ideas that the questioner wishes to bring before him. The dialogues of Plato are, as it were, philosophical dramas, in which the Socratic method of investigation is brought to bear upon speculative subjects. The form of the dialogue is but ill adapted to the modern state of science. Of the more eminent modern writers in this form, we may mention Erasmus in Latin; Lessing, Herder, and Wieland among the Germans; Petrarch and Machiavelli in Italy; Fénelon and Fontenelle in France; and Berkeley, Hurd, and Harris in England. Landon's *Imaginary Conversations* are a happy effort of this kind. When dialogue is combined with action, we have the drama.

**DIALYSIS**. See OSMOSE.

**DIAMAGNETISM**. The fact that iron is attracted by the magnet, has been known from very remote times; that bismuth exhibits a repulsive action towards the magnetic needle, has been now known for nearly 100 years. Dr. Faraday was the first (1845) to show that all bodies are more or less affected by magnetic influence, and his beautiful researches on the subject have opened up a new field in the domain of science. He found that the magnetism of bodies was manifested in two ways—either in being attracted by the magnet, as iron; or in being repelled, like bismuth. When a needle or slender rod of iron is suspended between the poles of a magnet being attracted by them, it takes up a position of rest on the line joining the two poles. When a substance behaves itself in this manner, it is said by Faraday to be *paramagnetic*, and to place itself *axially*. A rod of bismuth, on the other hand, being repelled by the poles of the magnet, comes to rest at right angles. Bismuth, and the like substances, he calls *diamagnetic*, and they are said to place themselves *equatorially*. These terms, being both definite and graphic, have been universally adopted. Magnetic is the term used by Faraday to indicate magnetism of either sort, although in general language it is understood to refer to paramagnetic bodies, such as iron, etc. Paramagnetic bodies,

then, are those which manifest the same properties with regard to the magnet that iron does; and diamagnetic bodies are those which, like bismuth, show opposite but corresponding properties; so that in circumstances where paramagnetic bodies place themselves axially, diamagnetic bodies place themselves equatorially; and where the former are attracted, the latter are repelled, and *vice versa*. A paramagnetic, therefore, not in the elongated form, but in a compact shape, such as a ball or cube, is attracted by either pole of the magnet, when suspended near it; a ball or cube of a diamagnetic, on the other hand, experiences, when so placed, repulsion. The paramagnetism of iron, nickel, and cobalt, becomes manifest in the presence of magnets of ordinary power; but the magnetism of most other substances is so feeble as to be developed only under the influence of the strongest magnets. As electro-magnets far exceed permanent steel magnets in strength, they are selected for investigations on the magnetism of bodies. The soft iron horseshoe of the electro-magnet is enveloped towards its extremities in coils of insulated copper wire which communicate with a galvanic battery by wires. The electro-magnet is fixed in an upright wooden frame. The ends or poles of the magnet rise slightly above the table or board which forms the upper part of the frame. In order conveniently to suspend substances between the poles, and to protect them while under observation from currents of air, a glass frame of simple construction is made to fit the table. The upper plate of the frame admits a wooden ring, into which an upright glass tube is fitted. The thread by which the needle is suspended is wound round a slender movable bobbin at the top, so that it can be elevated or lowered to the proper position. To modify and direct the action of the magnet, two pieces of soft iron are made to rest on the end faces; these are pointed at one extremity, and flat at the other, so that the force of the magnet may be concentrated in the points, when they are turned towards each other; or diffused over the opposite flat surface, when their position is reversed.

To observe the effect of the magnet on liquids, Faraday placed them in long tubes of very thin glass, and suspended them as in the case of solid needles. It was found that some arranged themselves axially, and others equatorially. The attraction and repulsion that liquids experience in the presence of the magnet has been prettily shown by Plucker. A large drop of liquid is placed in a watch-glass, and laid upon two poles of the magnet. If the liquid be paramagnetic, the surface becomes depressed at the interval between the poles, and heaped up over the extreme edges of them. A diamagnetic liquid, on the other hand, shows a depression at each edge of the poles, and a heaping up at the center.

The magnetic nature of flames and gases has been also studied. When the flame of a candle is brought between the poles of a magnet, it is repelled by them, and thrown out horizontally into an equatorial position. To ascertain the magnetism of gases, Faraday inflated soap-bubbles with them, and their para- or dia-magnetism was exhibited by their being attracted or repelled by the poles. He ascertained the same by causing the gases to flow out from glass tubes in the presence of the poles, when the peculiar magnetism of the gas was shown by its choosing an axial or equatorial means of egress.

The following list gives the kind of magnetism displayed by the more common substances:

*Paramagnetic*.—Iron, nickel, cobalt, manganese, chromium, titanium, palladium, paper, sealing-wax, peroxide of lead, plumbago, red-lead, sulphate of zinc, shellac, vermilion, charcoal, proto and per salts of iron, salts of manganese, oxygen, air.

*Diamagnetic*.—Bismuth, antimony, zinc, tin, cadmium, sodium, mercury, lead, silver, copper, gold, arsenic, uranium, tungsten, rock-crystal, mineral acids, alum, glass, litharge, niter, phosphorus, sulphur, resin, water, alcohol, ether, sugar, starch, wood, bread, leather, caoutchouc, hydrogen, carbonic acid, coal-gas, nitrogen.

The nature of the medium in which the body under examination moves, exerts a powerful influence on the nature and amount of the magnetism it exhibits; thus, if a glass tube be filled with a solution of the proto-sulphate of iron, and suspended between the poles, it will place itself axially. It will do the same if made to move in water, or a solution more dilute of the proto-sulphate of iron. It will be indifferent in a solution of the same strength; but it will place itself equatorially in a stronger solution. Thus, the same substance may appear paramagnetic, indifferent, or diamagnetic, according to the nature of the medium in which it moves. As a general rule, a body shows itself paramagnetic towards one less paramagnetic than itself, indifferent towards one equally magnetic, and diamagnetic towards one more paramagnetic than itself. The same takes place, *mutatis mutandis*, with diamagnetic substances. This has given rise to the theory, that there is no such thing as diamagnetism *per se*, and that bodies are diamagnetic only in media of greater paramagnetic power than their own. This view of the case is, however, rendered highly improbable from the fact, that diamagnetism is exhibited as decidedly in a vacuum as in any medium, and a vacuum cannot be supposed to possess magnetic properties of any kind.

**DIAMANTINO**, a significant name in the diamond districts of Brazil, indicates a river and two towns.—1. The river, apparently an affluent of the Paraguay, and, through it, of the Plate, rises in the province of Matto Grosso, being joined by the Ouro 70 m. to

the n.w. of Cuyaba.—2. Of the two towns, the more westerly stands at the confluence above mentioned, having a pop. of 4,500.—3. The more easterly town, again, is in the province of Minas Geraes, and stands amid the head-waters of the St. Francisco at an elevation of 5,700 ft. above the sea. It has about 7,000 inhabitants.

**DIAMETER**, in geometry, is generally used in speaking of curves, and its most general definition is, a straight line bisecting all parallel chords in a curve. In the circle, ellipse, and hyperbola, all diameters pass through the center, and are there bisected. Only the circle has all diameters equal; and each bisects the chords at right angles to it. In the ellipse, this last is only the case with the two diameters called the major and minor axes. In the parabola, all diameters are parallel to the axis. Many curves of the higher orders have no diameter at all.

We speak also of the diameters of solid bodies of a round shape. In the sphere, lines passing through the center are diameters, and so in the ellipsoid; they are all bisected in the center.

**DIAMOND** (corrupted from Gr. *adamant*, untamable, refractory), the most valuable of precious stones after the ruby, and the hardest of all known substances. It consists of carbon (q.v.), a simple or elementary substance, crystallized, and in its greatest purity. Diamonds are commonly colorless and clear like water; although sometimes, from some slight foreign intermixture, they are white, gray, yellow, green, brown, and more rarely orange, red, blue, or black. The luster is adamantine and very high; the transparency perfect in specimens perfectly free from foreign substances, the presence of which, however, even in very small quantity, mars it, and sometimes almost produces opacity. The D. becomes positively electric by friction, but is not electrified by heat, a test which sometimes serves to distinguish it from the topaz. Its specific gravity is about 3.6. Its primary form is a regular octahedron, but it appears also in rhombic dodecahedrons; and its crystals often have curvilinear faces and edges. Its structure is distinctly lamellar. It burns before the blow-pipe in air or in oxygen gas, combining with oxygen to form carbonic acid. Its hardness renders it incapable of being scratched by any other substance, and in cutting and polishing diamonds, diamond-dust is employed. The estimation in which it is held as a precious stone is due to its remarkable hardness, rarity, and brilliancy. The art of cutting diamonds, although long practiced in India and China, was not known in Europe till after the middle of the 15th c., when it was discovered by Louis van Berguen of Bruges. Previous to that time, diamonds were set without being cut, and in that state they have often a rough, dull, and uneven surface. Diamonds are indeed found not only in the form of perfect crystals, but also in rolled grains; and they are obtained partly from alluvial soils and the sands of rivers, and partly from rocks, chiefly a quartzite sandstone or conglomerate, in which they are often associated with gold. A number of localities in India have long been celebrated as productive of diamonds, particularly Golconda (q.v.); they are found also in Malacca, Borneo, and other parts of the east; nor were any diamonds procured in any other part of the world till the beginning of the 18th c., when they were discovered in remarkable abundance in the district of Serra do Frio, in the province of Minas Geraes, in Brazil. Previous to that time, diamonds found in Brazilian gold mines had been disregarded as mere pebbles; their nature became known in consequence of some of them accidentally finding their way to Europe. In 1829, they were discovered in the Ural mountains. They have also been found in Rutherford co., North Carolina; in Hale co., Georgia; in the province of Constantine, Algeria; in Australia; and in South Africa. Diamond mines consist in general of mere diggings and washings of alluvial deposits. In Brazil, the method pursued is to rake the alluvial matter backwards and forwards on inclined planes, over which a stream of water is made to run, till the lighter particles are carried away, when large stones are picked out by the hand, and what remains is carefully examined for diamonds. The work is carried on by slaves, and when a diamond of 17 carats is found, the slave who finds it is entitled to his liberty. Large diamonds are comparatively rare among those of Brazil, all the notable diamonds in the world being Indian. Brazil produces yearly from 25,000 to 30,000 carats of diamonds, of which, however, not more than 9,000 carats are capable of being cut, the rest being either very small or of inferior quality. The small and inferior diamonds are called *Bort*, and command a ready sale for their use in the arts, being pounded in a steel mortar, and much employed in the form of diamond-dust by lapidaries for cutting and polishing diamonds and all kinds of gems, and even for polishing rock-crystals for spectacles. Minute fragments or splinters of bort are also used for making fine drills, which are used for drilling small holes in rubies and other hard stones to be employed in watch-making, gold and silver wire-drawing, etc., and for piercing holes for rivets in china, in artificial enamel teeth, etc. The use of small diamonds by glaziers for cutting glass is well known. The diamonds so used are uncut, and they are so mounted as to act upon the glass not by an angle, but by a curvilinear edge of the crystal. The cut is only to the depth of about one two-hundredth part of an inch, but is sufficient to make the glass readily break in accordance with it.

Diamonds are cut into various forms, but principally into *brilliant*s and *rose diamonds*. The *brilliant* cut is the most expensive and difficult, but is also that which best brings out the beauty of the stone. It has an upper or principal octagonal face, surrounded

with many facets, and other things being equal, the greater the number of facets, the more valuable is the diamond. The lapidaries of the east, however, sometimes multiply facets to hide imperfections of the stone. *Rose diamonds* have a flat base, above which are two rows of triangular facets, the six uppermost uniting in a point. Rose diamonds are made of those stones which are too broad in proportion to their depth to be cut as brilliants. Stones still thinner are cut as *table-diamonds*. The art of sawing diamonds, when too thick in proportion to their surface, was invented by a Dutchman named Dalbeck in the beginning of the 19th century.

The value of diamonds is variously estimated. The rule generally given is to square the number of carats the diamond weighs, and then to multiply by the price of a single carat. Thus, a rough diamond of 12 carats weight, one carat being estimated at £2, would cost  $12 \times 12 \times 2 = \text{£}288$ . The value of a diamond is much increased by its being cut, although the actual weight is diminished. Beyond a certain weight, no rule of calculation can be applied, owing to the limited number of purchasers, and the most fabulous values have been assigned to famous diamonds. The price of diamonds varies according to the supply and changes in fashion, and is now lower than formerly.

There is a way of falsifying diamonds by joining an under part of some other stone to an upper part of genuine diamond. Some varieties of sapphire, hyacinth, and topaz, are often passed off for diamonds. The first two may be distinguished by their greater specific gravity, the latter by its becoming electric when heated. Rock-crystal, and glass or "paste" imitations, are lighter than true diamonds, and less hard and brilliant. The best test of a genuine diamond is hardness. Care must be taken, however, to avoid breaking off its angles, in testing it by scratching other substances with it, as, though hard, it is somewhat brittle.

Some particular diamonds, from their unusual magnitude, or from circumstances of their history, are of such interest as to entitle them to notice. The collection of the emperor of Brazil is said to contain an uncut diamond—the Braganza diamond—of the enormous weight of 1680 carats, or about 12 ounces; but it is suspected to be only a fine colorless topaz.—The largest diamond certainly known is that belonging to the rajah of Mattan, weighing 367 carats. It is egg-shaped, with an indented hollow near the smaller end. Many years ago, the governor of Borneo offered for it \$500,000, two war-brigs fully equipped, a number of cannon, and a quantity of powder and shot. But the rajah refused to part with it, the fortunes of his family being supposed to be connected with it, and the Malays ascribing to water in which it has been dipped the power of healing all diseases. Perhaps the most famous diamond is the Koh-i-noor (q.v.), once a boasted possession of the great Mogul, and now belonging to the queen of Great Britain. It is said to have weighed 900 carats in the rough; but now, after various cuttings, weighs 123 carats. The Orlov diamond, belonging to the Russian emperor, and which was once the eye of an Indian idol, is said to have weighed, when rough, 779 carats, but is now cut, egg-shaped, and weighs 102½ carats.—The Regent diamond, or Pitt diamond, which weighs in its cut state 136½ carats, is unrivaled in its limpidness and its form, its diameter and depth being nearly equal. It was found in Golconda, was brought from India by an English gentleman named Pitt, the grandfather of the first earl of Chatham, and by him sold to the duke of Orleans for £130,000. It decorated the hilt of the sword of state of the first Napoleon, was taken by the Prussians at Waterloo, and now belongs to the king of Prussia.—The Sanci diamond, weighing 106 carats, has a still more interesting history. It belonged to Charles the bold, duke of Burgundy, who wore it in his hat at the battle of Nancy, where he fell. A Swiss soldier found it, and sold it to a clergyman for a gulden. It passed into the possession of Anton, king of Portugal, who was obliged to sell it, the price being 100,000 francs; and it shortly afterwards became the property of a French gentleman named Sanci, whose descendant being sent as ambassador to Soleure, king Henry III. required the diamond as a pledge; but the servant who was carrying it to the king was attacked by robbers on the way and murdered, not, however, till he had swallowed the diamond. His master, fully confident of his faithfulness, caused his body to be opened, and found it in his stomach. This diamond came into the possession of the crown of England, and James II. carried it with him to France in 1688. Louis XV. wore it at his coronation.

Diamonds.

- 1, the Koh-i-noor; 2, Regent or Pitt diamond; 3, Grand Duke; 4, 5, vertical and lateral appearance of the brilliant diamond; 6, 7, vertical and lateral appearance of the brilliant diamond before being recut; 8, 9, vertical and lateral appearance of rose-cut diamond; 10, 11, the table-cut diamond.

In 1835, it was purchased by a Russian nobleman for half a million of rubles (£80,000). The Sanci diamond is said to have been the first diamond which was cut in Europe.

**DIAMOND BEETLE**, *Curculio imperialis*, a beetle or coleopterous insect of the tribe to which the name **WEEVIL** is generally appropriated, but remarkable for the splendor and exquisite beauty of its colors, in which it is thought to be unrivaled even among coleopterous insects. It is of a golden-green color, with two black longitudinal bands on the thorax, and several rows of depressed spots on the elytra (wing-covers), which exhibit a beautiful and sparkling green with intervals of black. It is a native of warm parts of South America.

**DIAMOND HARBOR**, the port of Calcutta for large ships, is situated on the left side of the Hoogly, about 30 m. below the capital, with which it is connected by an excellent road and by electric wires. As the adjacent country is swampy and unhealthy, the spot is marked only by a few native huts. The commercial value of the locality, however, is likely to increase, in proportion as the silting up of the river above impedes the upward navigation.

**DIAMOND NECKLACE**, THE, a wonderful piece of jewelry, made in Paris about the year 1775, and intended for Madame Du Barry, the favorite of Louis XV. She, however, was excluded from court on the death of Louis (1774), and before the necklace was finished. After being made, this beautiful ornament, adorned with 500 diamonds, was discovered to be so costly that no one could purchase it. It was valued at 1,800,000 livres, which in present sterling money is equal to about £80,000.

The prince-cardinal de Rohan, a wealthy, vain, and profligate man, persuaded by a woman named De Lamotte, who waited about court, that the queen (Marie Antoinette) regarded him with an eye of favor, became so infatuated with the idea that he was ready to do anything, however extravagant, in order to preserve this feeling in the queen. De Lamotte had stated to the cardinal that the queen was desirous of obtaining this glorious necklace, and that not having sufficient money just then, she would sign an agreement to purchase it if the cardinal would become security. The cardinal consented. The agreement was approved of and signed with the royal signature, as also with that of the cardinal, who, on the 1st Feb., 1786, carried off the treasure to Versailles, where it had been agreed the queen should send for it. On the following day, a person dressed in the uniform of one of the court valets, entered the apartments of the cardinal, and repeating as he entered the words, *de par la reine*, "in the name of the queen," he advanced to the table whereon the casket containing the treasure lay, and bore it away. In a few days De Lamotte, her husband, and the *soi-disant* valet, having all disappeared from Paris, were busily engaged separating the diamond necklace into portions, and selling them. The whole transaction had been a trick; the messages from the queen, verbal and written, were without foundation, the latter, indeed, being forged by the "valet," who was skilled in imitating handwriting. The plot was discovered by means of the maker of the diamond necklace, who, not receiving any money when the period of the first installment had arrived, went to court, demanding to know if the necklace had been delivered to the queen. In a few months the cardinal found himself in the Bastille, where those by whom he had been duped were already sent. In May, 1786, the trial of the prisoners was brought to a close. De Lamotte was branded on each shoulder with the letter V (for *voleuse*, thief), and was sentenced to be imprisoned for life. All the others were acquitted. The queen was falsely supposed by the populace of Paris to have been implicated in the plot, and the odium resulting from it was cast upon her, even at the last, when she sat on the cart that bore her through a raging and cursing mob to the guillotine.

**DIANA**, a Roman goddess, corresponding in most of her attributes to the Grecian Artemis. According to the myths, she was the daughter of Jupiter and Latona, and the twin-sister of Apollo. She was born, along with her brother, on Mt. Cynthus, in the isle of Delos, which till then had been a floating island, but was fixed by Neptune in its present place, that Latona might there give birth to her children in peace and safety from the persecutions of the jealous Juno. D. was worshiped by Greeks and Romans alike, as both a destroying and a preserving goddess. In the former capacity, she was represented as a full-grown virgin, armed with bow and arrows, with which she avenged herself on her enemies; as a preserving deity, she watched over the sick, and helped the unfortunate. Young girls, and women in childbirth, were the objects of her special care. She was herself beyond the allurements of love; and the ministers of her worship were vowed to lives of the strictest chastity. As sister of the sun-god Apollo, D. was regarded as the goddess of the moon; hence her Greek name *Selene*, and her Latin names *Lucina* and *Phœbe*. Her worship was conducted with splendid rites in different cities. Her temple at Ephesus was one of the seven wonders of the world. In Tauris (the Crimea), she was propitiated with sacrifices of human victims; and before her statue at Sparta, the public scourging of the Lacedæmonian youth used to take place. In Arcadia, she was looked upon as the special patron of hunting and all sylvan sports, and as such was represented in Greek works of art as a tall and handsome maiden, with long hair floating down her neck, drawing an arrow from her quiver with one hand, and with the other holding in a struggling deer. As goddess of the moon, she wears a long robe reaching to her feet, and bears on her brow a crescent moon.

**DIANA, TEMPLE OF**, at Ephesus, a magnificent structure built at the public charge, and recorded one of the seven wonders of the world. Chersiphron was the chief architect. According to Pliny, 220 years were spent before it was completed. It was 425 by 225 ft., covering more than two English acres, supported by 127 columns of white marble, 60 ft. high, each weighing 150 tons, and presented by as many kings. On the night of the birth of Alexander, it was fired by Erostratus, an obscure person, who did it solely to secure immortality for his name, and ever since "the aspiring youth who fired the Ephesian dome outlives in fame the pious fool who built it." Having been rebuilt, it was again destroyed by the Goths, 256 A.D.

**DIANE DE POITIERS**, 1499-1566; Duchess of Valentinois and mistress of Henry II. of France. When but 13 years of age she was married to the count of Maulvner, grand seneschal of Normandy, by whom she had two daughters. Her father was condemned to death for favoring the escape of the constable de Bourbon, but her tears and her beauty so prevailed with Francis I. that the father's life was spared. She was a widow 40 years old when she became the mistress of Henry (then dauphin), who was but half her age. At that time the duchess d'Etampes was the favorite of Francis, and the two women ruled the court; but when Henry became king, Diane was the real ruler, and at once sent her rival into exile. Notwithstanding the beauty and the rights of his wife, Henry was controlled by Diane during his whole reign. After his death she disappeared from public sight.

**DIANO'**, a t. of southern Italy, in the province of Salerno, 45 m. s.e. of the town of Salerno. It occupies a beautiful situation on an isolated hill overlooking the river Calore, and in the fertile vale of Diano, which takes its name from the town. There are several churches and an old castle. The commune has a pop. of about 6,000.

**DIANTHUS**. See **PINK**.

**DIAPASON**, a term in music by which the ancient Greeks designated the octave. In modern music, D. is used to denote the range, or compass of the voice, or of an instrument. The French use the term as equivalent to *pitch*. D. is also the English name given to certain stops of pipes in the organ, of 8 ft. pitch, which are considered the fundamental stops, of which there are generally two—a stopped D. and an open D. on each manual. See **ORGAN-BUILDING**.

**DIAPASON REGULATOR**. The French, who give the name of *diapason* to the tuning-fork, have lately made attempts to use that instrument in connection with clockwork, partly as a means of counting very small intervals of time. M. Duhamel made an arrangement in which a cylinder, by means of a screw-tapped end, was made to advance a little in the direction of the axis; this cylinder was covered with blackened paper, and was rotated by means of clockwork. A diapason had a style or marker, made of a small bit of pointed spring, fixed to the end of one of the prongs. On the diapason being sounded in the usual way, and the spring placed lightly against the cylinder, the style traced a sinuous white line on the black paper. The sinuosities became visible representatives of minute intervals of time, the prongs vibrating possibly hundreds of times in a second. M. Lissajous devised an electrical apparatus to prolong the vibrating of the prongs; but it was too complexed for practical use. M. Breguet then proposed clockwork for this purpose, superseding the pendulum and the spiral spring by a diapason. The diapason regulates the rate of motion of the train of wheels by the equality of the vibration of the prongs, while the train of wheels tends to increase the time during which the prongs vibrate and sound. An index carried by an arbor round a dial, may be made to count or record the vibrations. Breguet's experiments have gone as far as instruments giving 200 simple vibrations (100 double or to-and-fro vibrations) per second. There are means of making the diapason more or less acute in sound, or with a greater or less number of vibrations in a second, by mechanical treatment of the prongs: it can, by a proper distribution of metal, be made to yield any required note within certain limits; and thus, with the aid of the style, the paper, and the cylinder, it may be made to give a kind of visible existence to excessively minute intervals of time, such as  $\frac{1}{300}$ th part of a second. Fuller details are given in Breguet's description of the apparatus in the *Revue Chronometrique*.

**DIAPER** (Ital. *diapro*), a term derived from *jasper* or *diasper* (see letter D), which stone being much used in ornamenting jewelry, originated the Mid. Lat. name *diasprus*, for a texture ornamented or variegated in an analogous way. In textile manufactures, the term is applied to fabrics with patterns of geometrical regularity, such as are produced by the kaleidoscope, woven in their texture, and produced with shafts and heddles, without the Jacquard machine. In architecture, **DIAPER-WORK**, or **DIAPERING**, is a kind of decoration applied to plane surfaces, and consists of a small pattern either of flowers, leaves, or arabesques, carved or painted. The flower, or other object, is generally inclosed in a small frame, and these frames, which touch each other at the edges, constitute in themselves a sort of mathematical diapering. When the pattern is carved, it is generally sunk; and when painted, it consists of a darker shade of the same color as the plane surface, by which the effect of shadow is communicated to it.

**DIAPRÉ** is applied in heraldry to fields and charges, relieved by arabesque and geometrical patterns. These patterns were generally of a darker shade of the same

ointment. This being merely an ornamental device, not affecting the heraldic value of the objects to which it was applied, was generally left to the fancy of the painter.

**DIAPHANOSCOPE** (Gr. *diaphanos*, transparent; *skopeo*, I see), a dark box, suitably constructed for exhibiting transparent photographs or other pictures. It may or may not be furnished with a lens.

**DIAPHORESIS** (Gr.), the cutaneous perspiration, whence

**DIAPHORETICS**, remedies to excite the secretions of the skin. The simplest of all D. are baths, which may be either warm baths of water, or of vapor, either simple or medicated. See **BATHS**. The most powerful of all, however, as regards educing perspiration, is probably the so-called Turkish bath, which consists essentially in the use of a sweating process, by means of air heated to a temperature of 140°, or even more. The following remedies, used internally, are powerful D.: antimony, ipecacuanha, opium (these three either singly or in combination); ammonia, and the carbonate or acetate of ammonia (spirit of mildererus), sarza, guaiacum, dulcamara, and sassafras. On most of these substances, special articles will be found. A favorite formula is Dover's powder, consisting of a grain of opium, and a grain of ipecacuanha in each ten grains of the powder. This in doses of from five to eight grains, followed by warm drinks and plenty of blankets in bed, usually produces copious perspiration, and is very soothing and useful in many commencing inflammatory and febrile complaints. James's powder, in doses of from 3 to 8 grains, is often added to the above in domestic prescriptions; but neither of these medicines should be used rashly, as in certain states of the system they may prove dangerous; and they should never be given to very young children.

**DIAPHRAGM** (Gr. *diaphragma*, a partition). This is the name applied in anatomy to designate the transverse muscle which, in man and the mammalia generally, separates the cavity of the thorax or chest from that of the abdomen or belly. In form, it is nearly circular; it is fleshy at its edges, tendinous in its center, and ending in a point below. In front, it is attached to the ensiform cartilage of the sternum, or breast-bone; laterally, to the inner surfaces of the six lower ribs; and posteriorly, to two tendinous arches on either side, termed the *ligamenta arcuata*, and to the anterior surface of the bodies of the second, third, and fourth lumbar vertebræ on the right, and only the second and third on the left side; these origins from the vertebræ forming two large fleshy bellies (termed the *crura*), which ascend to join the central tendinous portion. The D. presents three principal openings: one quadrilateral, in the tendinous center, for the upward passage of the inferior vena cava; one of an elliptic shape, formed by the two crura for the œsophagus and pneumogastric nerves; and a third for the aorta, the azygos vein, and the thoracic duct.

The diaphragm is in relation superiorly with the pleuræ and pericardium, inclosing the lungs and heart; inferiorly, on the left side with the stomach and spleen, on the right with the convex upper surface of the liver; posteriorly, with the kidneys and supra-renal capsules and the duodenum; and by its circumference with the ribs and intercostal muscles, with the sternum, and with the vertebral column.

It is convex superiorly, and concave inferiorly. When it contracts, its upward convexity approximates to a plane surface, and the cavity of the chest being thus enlarged, air rushes in to fill the partial vacuum, and expands the lungs during the act of inspiration. It is thus an inspiratory muscle, and is the sole agent in tranquil inspiration. The enlargement of the thoracic cavity caused by the contraction of the diaphragm, must obviously be associated with a corresponding diminution of the abdominal space. Hence this muscle, by its action on the abdominal viscera, aids in the expulsion of the feces and urine.

Spasmodic action of the diaphragm produces hicough and sobbing; and in laughing, the alternate contractions and relaxations of this muscle occur with increased rapidity. Stoppage of the action of the diaphragm, whether from great external pressure or from paralysis, is very speedily fatal.

**DIAPHRAGM**, a partition with a hole in it, employed, not only in landscape and portrait lenses for photography, but also in telescopes, microscopes, and other optical instruments, for the purpose of cutting off the superfluous rays of light, and producing greater intensity or sharpness of the image, as well as to correct aberration.

**DIAPHRAGM SHELL**. See **SHELL**.

**DIARBEEKIR**, a t. of Asiatic Turkey, capital of a vilayet of the same name, is situated on the right bank of the Tigris, at a short distance from the river, the intervening space being occupied by rich gardens; lat. 37° 55' n., long. 39° 52' east. The town, which is circular in shape, covers a considerable area, and is surrounded by high strong walls, flanked with towers, and pierced by four gates. The streets are dirty, and the houses for the most part are built of rough stone, plastered with a composition of mud and straw, but some of the better class are of black basalt. It has numerous handsome mosques, klans, and bazaars, and five Christian churches. Extensive manufactures of silk, cotton, and other goods, affording, with an active commerce between Aleppo and Bagdad, employment to about 40,000 families, were at one time carried on here; but the manufactures and trade have now greatly declined, and the population of D. does not amount to more than 8,000 families, 6,300 of whom are Turkish, the rest being Greek,

Armenian, Catholic, and Jewish. The silk manufacture, which is now the staple, is said to be improving. D. occupies the site of the ancient *Amida*, which was a place of importance in the reign of Constantius, by whom it was strengthened and enlarged. In this reign it was taken by the Persians, from whom it was again captured by the Romans; but in 502, the Persians once more became masters, and put 80,000 of the inhabitants to the sword. After many vicissitudes, it passed into the hands of sultan Selim in 1515. Many Roman and Saracenic remains still exist here.

**DIARRHÆA** (Gr. *dia*, through, and *rheō*, I flow), a disease or rather a tribe of diseases, characterized by an increase in the discharges from the bowels, which are usually unduly liquid, sometimes overcharged with bile, and sometimes the contrary. Diarrhœa has many varieties and many causes; but the whole tribe of diarrhœal diseases present certain relations in common, which have been studied of late years to a considerable extent from the preventive or sanitary point of view. Thus, it is observed of all of these diseases, without exception, that they are more apt to prevail during summer and autumn than during the earlier seasons of the year; and it is also well established that their prevalence is to a great extent dependent on the intensity of the solar heat, so that a temperature above 60° F. seems to be almost essential, under ordinary circumstances, to their epidemic diffusion. Moreover, it has been shown that the decomposition of organic matters in the neighborhood of human dwellings, and the introduction of the products of decomposition into the food, drink, or air used by the healthy, has been a direct exciting cause of diarrhœa in a great number of instances where the disease has been locally epidemic; from which it is inferred that the real source of diarrhœal diseases is usually to be found in a morbid poison closely associated with the process of putrefaction, although not, perhaps, necessarily generated during that process. It has been noticed that cold and wet seasons are the least favorable to the production of diarrhœa, which is explained on the theory above alluded to by the rapid removal in such seasons of all organic debris; and there is little doubt that this explanation is correct, as the converse is equally true, the combination of heat with long continued drought being almost sure to waken into life the epidemic seeds of diarrhœa. Again, it is noticed that where drainage is imperfect, and drinking water impure, diarrhœal diseases are specially apt to occur (see *CHOLERA*); the class of the population most apt to be affected being those who occupy low levels, or who are otherwise exposed to the influence of this aqueous or gaseous poison. Infants are especially apt to suffer from diarrhœa, and a large number of the infantile deaths in many English towns are caused either directly by this disease, or by the abuse of stimulants and narcotics for its cure.

Diarrhœa is either simple, bilious, or choleraic; the last form has already been discussed. See *CHOLERA*. The ancients applied the name *lientery* to a diarrhœa in which the dejections consisted of matters not digested, or very partially so; this form is, however, very unusual, at all events in this country. Dysentery (q.v.) is also a form of diarrhœal disease; as is the form of fever (q.v.) called gastric, typhoid, or enteric fever. Simple and bilious diarrhœa probably often differ only in degree; they are both distinguished from the advanced stages of cholera and dysentery by the presence of abundance of biliary coloring matter in the stools, and by the absence of the distinctive features of the other two diseases as described elsewhere. Diarrhœa frequently depends on organic disease, either of the intestines themselves, or of the liver, kidney, or spleen. It is also one of the most common symptoms of the advanced stage of consumption (q.v.).

When diarrhœa is plainly the consequence of improper food or drink, when it is very recent, when the strength of the patient is not much impaired, when there is much griping pain or distension of the belly, when the evacuations are very unnatural in character, and especially when they are dark colored and very fetid; when the disease has been preceded by habitual constipation (q.v.), and when there is no organic disease to be discovered, it is well to let diarrhœa run its course, at all events for a time, and either to aid it by small doses of very simple laxatives, or, at all events, to abstain from hastily checking the discharge, which in these cases is to be regarded as a truly curative and beneficent process, calculated to disburden the system of some poisonous or deleterious substance, and only requiring time for the restoration of the patient to health. In other cases, especially of febrile diarrhœa, an emetic of ipecacuanha at the very beginning will sometimes remove the disease with remarkable rapidity; and in most forms of diarrhœa it may be alleged that this medicine (in doses of from one to five or even ten grains, is well borne. Sometimes it is combined with opium in the form of Dover's powder. Vegetable astringents, as catechu, kino, tannin, matico, logwood, are also much employed both in acute and chronic cases; some prefer the acetate of lead, with opium (which, however, is perhaps more suitable to dysentery). It should be observed that in some forms of diarrhœa the use of opium, though a most powerful remedy, is contraindicated by the state of the constitution; it should in no case be largely given without medical advice. In many chronic cases the metallic tonics and astringents are of service—e.g., iron, sulphate of copper, zinc, and bismuth. In a very large class of cases, especially of infantile diarrhœa, depending upon a too acid state of the secretions, the leading remedy is chalk, either in powder or in the very serviceable form of the *mistura cretæ* (mixture of chalk) of the pharmacopœias, from one to three dessert-spoonfuls of which may be given after every disturbance of the bowels. Lime-water,

mixed with milk in the proportion of one to four or five, is easily given to very young children, and serves nearly the same purpose.

**DIARY** (Lat. *diarium*, from *dies*, a day), means simply a daily record. It does not, however, comprehend every sort of daily record, but only such as have reference to the writer personally. In it the *litterateur* inscribes the daily results of observation, reading, or thought; to the mercantile man, it serves the purpose of an order or day book; while the physician finds it indispensable as a register of engagements. The use of diaries has become so general, especially in England, that the making of them now forms an important branch of the book-manufacture. Let's & Co., of London, issue annually upwards of a hundred varieties of diary, from the large folio to the smallest pocket volume. The usual diary may be described as a book with a separate blank space for every day in the year, these spaces varying in size and form, as the particular bent or profession of the diarist may render necessary. Bound up with these diaries is a summary of the important events of the past year, a list of the acts of parliament passed during the previous session, an enumeration of public holidays, terms, etc., a great amount of valuable information regarding banking and insurance businesses, with a vast quantity of miscellaneous memoranda, so that the proprietor possesses in one book a D. and an almanac.

Diaries have often furnished the historian with invaluable material, supplying the absence of public records, and furnishing minute and graphic details of the social condition and of the secret springs of public events that are not to be looked for in more formal records. Perhaps the most notable in this respect are the diaries of Evelyn and Pepys.

**DIASCHIS'MA**, the Greek name of a small musical interval which only appears in the mathematical calculation of greater intervals. The D. is, (1) the difference between the great half tone and the small *limma*, or the remainder when the latter is subtracted from the former, 2,048:2,025; (2) the difference between the *diesis* and the *syntonic comma*, also 2,048:2,025. The D. and the small *limma* added together always make the greater half tone, or 16:15; and the *syntonic comma* added to the D. always make the *diesis*, 128:125.

**DI'ASTASE** is a peculiar ferment developed during the germination of all seeds. An impure solution of D. may be procured by adding one part of hot water to two parts of ground malt (see BEER), or freshly germinated barley, and, after standing for a short time, straining through a cloth. The proportion of D. in malt is not more than 1 part in 500 parts, and yet it performs important functions. Thus D. has a powerful action upon starch, and at a temperature of 150° Fahr. 1 part is considered powerful enough to change 2,000 parts of starch into dextrine, and then into grape sugar. When obtained separately, D. is a white tasteless substance. See GERMINATION.

**DIATHERMANANCY**, a word used to express that quality in bodies by which rays of heat are allowed to pass through them; in other words, it may be called "transparency" to heat. More correctly speaking, D. has the same relation to radiant heat that transparency has to light. Bodies which have the property of D. are called diathermanous bodies. The earliest observers of the phenomena of D. supposed that the diathermanous body absorbed the rays of heat and then gave them out; but the fallacy of this idea was shown by Prévost, who ignited substances by rays of heat after passing them through ice. The phenomena of D. have, however, been more extensively examined by Melloni, Tyndall, Bunsen, Kirchhoff, and Balfour Stewart. The experiments of Melloni, who was the pioneer in the investigation, were of a brilliant character, and the apparatus used by him is a good example of that which has been used so effectively of late years in the rapid advancement of modern science. The thermoelectric pile of Nobili was employed to measure the rays of heat, and compare those which were passed through different substances with those passed through air alone. He found, among other things, that rock-salt was almost perfectly diathermanous; there was a loss of only 7.7 per cent, which he attributed to reflection. The following table shows the D. of various solids, and also that their D. varies with the intensity of the heat which is the source of the rays. The substances were  $\frac{1}{16}$  of an in. thick.

Substances.	Locatelli Lamp.	Incandescent Platinum.	Copper at 752° F.	Copper at 212° F.
Rock-salt.....	92.3	92.3	92.3	92.3
Fluor-spar.....	72	69	42	33
Beryl.....	54	23	13	0
Iceland spar.....	39	28	6	0
Glass.....	39	24	6	0
Rock-crystal.....	38	28	6	3
Smoky quartz.....	37	28	6	3
Carbonate of lead.....	32	23	4	0
Sulphate of baryta.....	24	18	3	0
Feldspar.....	23	19	6	0
Borate of soda.....	18	12	8	0
Selenite.....	14	5	0	0
Alum.....	9	2	0	0
Ice.....	6	0.5	0	0

The equal D. of rock-salt to the rays of heat of different degrees of intensity as shown in the above table was taken by Melloni as evidence that its D. was perfect. Rays of very low refrangibility, however, will not all pass through rock-salt. Fluor-spar is seen to be comparatively diatheomanous, but Iceland-spar and glass show very great variation in D. to rays of different intensity. Feldspar does not vary much in property from them, but alum and ice are almost completely *atheomanous*. The following list shows the percentage of rays transmitted through liquids, held in glass cells,  $\frac{3}{8}$  of an inch thick:—Bisulphide of carbon, 63; bichloride of sulphur, 63; oil of turpentine, 31; olive-oil, 30; naphtha, 28; oil of lavender, 26; sulphuric ether, 21; alcohol, 15; acetic acid, 12; distilled water, 11.

After rays of heat have been passed through a body, it will then pass through a second body of the same kind, a phenomenon which might be expected from the nature of radiation. The rays being already sifted, and those transmitted which the molecular structure of the body will allow to pass, they possess the wave-lengths required to make their way between the molecules of the medium. Another quality rather more remarkable, which bodies possess, is, that they are *atheomanous* to rays of heat which are generated in the same substance. Thus rock-salt is nearly *atheomanous* to heat radiated by rock-salt. The absorbing and radiating powers of bodies are reciprocal and equal; therefore the D. of a body is inversely proportional to its radiating power. The investigations of Tyndall on the D. of various liquids and gases possess great interest. He found that as a rule elementary bodies were more diatheomanous than compound bodies. A solution of iodine in bisulphide of carbon placed in a prism of transparent rock-salt was found to transmit 99 per cent of all the rays of heat emitted by a non-luminous body. Elementary gases and their mixtures were found almost perfectly diatheomanous, while many compound gases were diatheomanous only to rays containing much light. The amount of heat transmitted by nitrous oxide gas is only  $\frac{2}{35}$ th of that which will pass through dry common air, a proof that the atmosphere is merely a mechanical mixture. The following list shows the relative absorbing power of various gases, or their D. in inverse proportion: Air, 1; oxygen, 1; nitrogen, 1; hydrogen, 1; chlorine, 39; hydrochloric acid, 62; carbonic oxide, 90; carbonic acid, 90; nitrous oxide, 355; marsh gas, 403; sulphurous acid, 710; olefiant gas, 790; ammonia, 1195. These gases are all perfectly diatheomanous to luminous heat. The above numbers were obtained only with heat of low refrangibility. These gases were held in tubes of rock-salt. If glass had been used, it would already have sifted out all the rays to which these gases are *atheomanous*, and the results above indicated would not have been obtained. Ozone, which is an allotropic condition of oxygen (q.v.), was found to be very *atheomanous*. But on heating the ozone it became perfectly diatheomanous like oxygen. This proves that ozone is not, as some have supposed, a compound of oxygen and hydrogen, because the heating would produce some vapor, and this would prevent the contents of the tube from being diatheomanous, for aqueous vapor was found to be quite opaque to the dark rays of the spectrum, although diatheomanous to the luminous rays. The subject of D. has much interest in relation to the study of meteorology, and the effects of moisture on climate.

#### DIATHERMANOUS. See HEAT.

**DIATHESIS** (Gr. *dia*, through, and *tithēmi*, I place or arrange), a Greek word signifying a disposition or arrangement, and applied by the old medical authors to the predisposition or constitution of the body which renders it prone to certain diseased states. Thus the tubercular, scrofulous, gouty, rheumatic, cancerous, or calculous diatheses, are described as something different from the corresponding diseases, but leading to these as natural or probable consequences, under certain conditions or exciting causes. The study of diathesis apart from existing disease, however, is almost always unsatisfactory, and leads to over-refinement and the pursuit of intangible abstractions, without due regard to evidence; inasmuch as the existence of a state which *is not* disease, but *leads to* disease, can rarely be established upon an unassailable basis.

**DIATOMACEÆ**, or **DIATOMS**, a group of organized beings, now generally regarded as belonging to the vegetable kingdom, and ranked as a sub-order of *algæ*; but formerly reckoned among animalcules, a view of their nature still entertained by some naturalists. Lindley makes D. an order of his *algal alliance* of thallogenous plants, including *desmidiæ* (q.v.) as a sub-order, and distinguishing the true D. as another sub-order, under the name *cymbellæ*. The D. are generally of a brown color, although they not unfrequently become greenish when dry. They are remarkable for their siliceous covering, composed of two pieces or valves, and their angular shape, and are among the most beautiful and interesting of microscopic objects, exhibiting great variety of markings—striae, dots, etc.—regularly and symmetrically arranged. The valves, or pieces of the siliceous covering, are always equal in length, but their sides often differ much in breadth. All within appears to be only a single cell; but many of these cells are often united or in contact, according to some mode of arrangement characteristic of the particular species. D. are found both in salt and fresh water, also on the surface of damp rocks and walls, garden-paths, flower-pots, the glass of hot-houses, etc. They may generally be obtained in great numbers by allowing water in which they exist to stand for a few hours, and then pouring off all except the more muddy or slimy part at the bottom.

They may often be seen to move a little in the water or slime in which they exist, particularly those of most elongated form; and this was once regarded as a very conclusive evidence of their animal nature, but is now believed to be no more so than the movements of vegetable zoospores, and to be owing to their imbibing and emitting fluids in the processes of their vegetable life. They increase by division (whence the name diatomaceæ, Gr. through-cutting), which takes place not transversely but longitudinally; and the lines which mark its progress are almost always visible in them. In this process, new siliceous valves are formed along the line of division, the old valves remaining on the outer sides, and each new diatom cell having an old valve and a new one. True reproduction takes place by conjugation (q.v.), and by the formation of *sporangia* (see Spore). D. very rapidly putrefy, but their siliceous shields resist decomposition more perfectly than almost any product of organic nature, and are found in immense numbers in many marls, clays, and rocks. They are capable of resisting even the action of fire, and of the gastric-juice of the stomachs of animals, and are found in pumice and volcanic ashes, and in guano. The abundance of the D. as existing organisms, corresponds with what we infer from their remains in the oolite, chalk, etc., as to former geological periods. Britain is known to possess hundreds of existing species. Dr. Hooker found them in such numbers in the Antarctic ocean as to give an ochreous brown color to its surface as far as the eye could reach, and to the icebergs floating in it; whilst a submarine deposit is in process of formation, composed of their siliceous shields. Thus these minute organisms, unimportant as they may be deemed individually, fill no insignificant place, collectively, in the general scheme of creation.

*Fossil D.* have been observed in strata of every age. Though so minute in the individual, they form, in the aggregate, considerable thicknesses of rock—they have, in fact, in common with the associated and nearly as minute and simple organisms of the animal kingdom, the foraminifera, produced greater changes, and left more lasting records than any effected by higher members of either kingdom. In the older rocks, D. have not been noticed in any quantity, their existence, however, in the clay-slates of the lower Silurians was discovered by Mr. A. Bryson, and has been subsequently noticed by other observers. In tertiary strata they occur in abundance. There is good reason for believing that the siliceous substance of flint was obtained, to a large extent, from these organisms; many of their frustules may yet be discerned in it. Tripoli-stone consists entirely of their siliceous plates, hence its value as a polishing agent. Several extensive deposits of tripoli are found in Bohemia—one at Egea is two miles in length, and averages 28 ft. in thickness; another at Bilin, forming the upper layer of a hill, is 14 ft. thick; it is composed chiefly of a species of *gallionella*, with specimens of *navicula*, etc., as many as forty-one thousand millions exist in every cubic inch of the stone! The city of Richmond, in Virginia, is built on a stratum of diatomaceous earth, 18 ft. thick. Similar deposits are found in different localities in Britain, as at Premnay, Dolgelly, Lough Mourne, Raasay, and Muil. From the last locality, Gregory has given a catalogue of 150 species. The whitish powder of which the deposit consists is called in Sweden Bergmehl (q.v.), and is, in seasons of scarcity, mixed by the poor with their food, though probably without any advantage, save increasing its bulk. D. occur in more or less abundance in marl, peat, guano, estuary mud, and other recent deposits.

**DIATONIC**, a term used in the science of music, originally from the Greek, meaning "by tones," or "from tone to tone." The diatonic species of the ancient Greeks—apart from their chromatic and enharmonic species—formed the foundation of their whole system of music, and was arranged in tetrachords composed of one semitone and two whole tones. The diatonic scale of modern music is a combination of the Greek tetrachord, forming a succession of sounds progressing from degree to degree, by tones and semitones in a certain fixed order, neither omitting nor repeating; the position of the semitones varying, as the scale is major or minor.

**DIATONIC SCALE OF COLORS**, the seven primary colors of a solar spectrum, or rather the spaces occupied by them, which Newton supposed to be of the same length as the strings that sound the diatonic scale in music. The theory is not well founded.

**DIATRIBE** (Gr. *diatribè*, a disputation, or critical exercise) was a name originally given to a critical examination of a literary work, and at a later period to a bitter and violent criticism, either written or spoken, on any subject, in any department of literature.

**DIAZ**, BARTOLOMEO, a Portuguese navigator of noble birth, who flourished during the latter half of the 15th century. His residence at the court of king John II. brought him into contact with many scientific men, among others the German cosmographer Behaim (q.v.). D. took a great interest in geographical discovery, and his knowledge and abilities were so highly estimated, that the king gave him the command of two vessels with a view to following up the discoveries already made by Portuguese adventurers on the w. coast of Africa. D. soon reached the limit which had been attained in s. Atlantic navigation, and first approached land in 26° s. lat. After disembarking at various places, and taking possession of the shores in the name of the Portuguese king, he sailed round the southern extremity of Africa without suspecting it, and cast anchor at the mouth of the Great Fish river, a little to the e. of Algoa bay. A storm now rose, and drove him into Algoa bay. He there found, near Port Elizabeth, his

companion-vessel, from which he had been separated before rounding the cape; but unfortunately the greater part of its crew had been murdered by the blacks. He now, for the first time, noticed his discovery, and called the cape, in remembrance of his danger, *Cabo de todos los tormentos* (Cape of all the Storms)—a name which the king of Portugal afterwards changed into its present, *Cabo de Buena Esperanza* (Cape of Good Hope). D. arrived in Lisbon Dec., 1487, and was at first greeted with enthusiasm, but soon saw Vasco da Gama preferred before him, and was compelled to act under the latter in the grand expedition of 1497. Vasco da Gama even sent him back to Portugal after they had reached the Cape Verd isles, so that he had no share in the honor of discovering a maritime route to the Indies. Three years after, he joined the expedition of Cabral, the discoverer of Brazil, but was lost in a storm, 29th May, 1500.

**DIBBLE AND DIBBLING.** The common garden dibble is an implement too well known to require any lengthened description. A round piece of wood, about an inch and a half in diameter, sharpened at the point, is the most simple and common form. To allow it to be more easily pressed into the ground, a handle is usually added. This is all that is needed for a garden dibble. In some parts of England, where labor is plentiful, large breadths of wheat are put in with the dibble. Several dibles are usually joined together, and made of sufficient length to enable a man to perform the operation, as he walks backwards, without much stooping. Children follow with the seed, and drop two or three grains of wheat in every hole. The dibbler is often used to put in beans. By dibbling, a considerable saving of seed is effected. From one bushel to six pecks of wheat is the usual quantity required to sow an acre. Dibbling is thought to be advantageous for light lands which are in good condition. More recently, several ingenious machines for dibbling have been constructed. The one most worthy of notice is Newberry's horse-dibble, which sows from one to seven rows, and accomplishes the operation with great nicety and accuracy. Being an expensive machine, however, it has not come into general use. Dr. Newington has invented a hand-dibble, a very perfect implement of its kind; the same machine makes the holes and deposits the seed at once. This has been a useful article on small holdings, and it is the greatest favorite at the present moment.

Dibbles of every kind are unsuitable for stiff or clayey soils; the soil, compressed and hardened around the hole which they make, not readily admitting the young fibers of the root, and retaining water to the injury of the young plant.

**DIBBS**, the English name of a game of great antiquity, played by boys and girls; and in Russia, as is described by Dr. Clarke, it is played sometimes even by old men. It consists in throwing up the small joint-bones of the legs of sheep, and catching them first on the palm and then on the back of the hand. The antiquity of this simple kind of play is proved by figures on Grecian vases, on which females are seen kneeling and engaged in the sport. In Scotland, where the game is more usually played with small pebbles or shells, it is called "the chucks."

**DIBDIN**, CHARLES, musician and poet, was b. at Southampton in 1745, educated at Winchester, and at the early age of 16 made his literary *début* in London, by writing an opera called *The Shepherd's Artifice*, which was produced at Covent Garden theater, of which he afterwards became musical manager. In 1789, he commenced giving a series of musical entertainments in the city, entitled *The Whim of the Moment*, which acquired a great celebrity. After several vicissitudes, he withdrew, in straightened circumstances, from public life in 1805, when government granted him, in consideration of his literary merits, a pension of £200. He died in 1814. D. is an admirable writer of sea-songs, of which he composed about 1200. Neptune, and not Apollo, seems to have inspired him. In fact, he is the only song-writer who has reached the heart of "the mariners of England." His verses smack of the briny deep, and reflect with astonishing felicity the easy, childlike virtues and the fearless courage of the English tar. It is known that they had a great effect during the war between France and England in supplying the navy with volunteers, and they have even been quoted in mutinies to the restoration of order and discipline. Among D.'s happiest pieces are *Poor Jack* and *Poor Tom Bowling*. The last edition of D.'s songs, with a memoir by T. Dibdin, illustrated by G. Cruikshank, appeared in 1850 (3d ed. 1863). D. also wrote a great number of dramatic pieces, etc.—He left two sons, CHARLES D. (d. 1833) and THOMAS D. (d. 1841), both of whom composed songs and dramas.

**DIBDIN**, Rev. THOMAS FROGNALL, nephew of Charles D., the famous writer of sea-songs, was b. at Calcutta in 1776. He lost both his parents when hardly four years of age, and was brought up by his mother's brother, a Mr. Crompton. He studied at St. John's college, Oxford, but left the university without taking a degree. After a short and unsuccessful career as a lawyer, he entered the church in 1804, and from that period until his death, 18th Nov., 1847, continued to labor as a bibliographer with a diligence that would have been more commendable if it had been accompanied with a stronger judgment and a greater accuracy. D.'s principal works are an *Introduction to the Greek and Roman Classics* (1802), *Typographical Antiquities*, 4 vols. (1810–19), *Bibliomania* (1811), *The Bibliographical Decameron* (1817), *Bibliotheca Spenceriana* (1814), *Bibliographical, Antiquarian, and Picturesque Tour in France and Germany* (1821), *The Library Companion* (1824), and *Reminiscences of a Literary Life* (1836). All D.'s books contain valuable and

rare information, but are far from trustworthy in matters of detail. Many of them are exquisite in typography and artistic decoration.

**DIBRANCHIATES**, a division of cephaloid mollusks, having two gills or branchiae, an ink-gland, and nearly always a rudimentary internal shell, such as the cuttle-fish, the octopus, the squid, and the argonaut, and the extinct belemnites. The female argonaut has a single-chambered shell not connected with the body, for the protection of her eggs. With this exception, they are naked.

**DICÆUM**, a genus of beautiful birds, which are best known in India and Australia. Their nests are purse-shaped and made from the down of plants. They fly with great rapidity, and are remarkable for their sweet and long-drawn-out notes.

**DICAST**, a body of 6,000 Athenian citizens chosen annually by lot from the whole people, except slaves, to assist in the administration of justice. They were divided into 10 sections, each section having the powers and performing the duties of a court of justice. The evidence in a cause was taken beforehand, and the members of the D. were kept in ignorance of the cases to come before them, being sworn, as jurors are in the present age, to decide according to the law and the facts.

**DICE** (plural of die), small cubes of bone or ivory, marked on their six sides with black dots, from one up to six in number. Two dice are employed in certain games of chance, such as backgammon; also in throwing for high stakes, or settling some dispute in which the decision is referred to the highest number thrown. In this latter point, the throwing of dice is equivalent to what is usually spoken of as "casting lots." The throwing of dice is in all cases effected by means of a small tubular box, which, held in the hand, is shaken at will by the player. When the dice are true cubes, there is no plan by which any kind of shaking can bring out a desired number. In order to repress gambling, and secure players against deception, the state, by the act 9 Geo. IV. c. 18, imposed a duty of 20s. on each pair of properly made dice, which were accordingly stamped, and a penalty was imposed on the sale of unstamped. Nevertheless there appears to have been a pretty free sale of unstamped dice under the name of "bones" at an insignificant price. In 1862, the stamp-duty was abolished, yet the repeal of the restriction has not to any extent stimulated the use of dice. Unscrupulous gamblers adopt the odious practice of loading dice, by plugging them with lead on a particular side, so that the higher numbers may turn up. Where there is any suspicion of this trick, the thrower should be requested to turn down the mouth of the box abruptly, to prevent the dice from rolling, and improperly adjusting themselves. See **GAMBLING**.

**DICÆ**, the goddess of justice in Greek mythology, daughter of Zeus and Themis, and sister of Eunomia. The tragedians represent her as an avenging and rewarding deity.

**DICENTRA**, the name of certain showy herbaceous perennials found in the United States and elsewhere. A curious specimen is known by the name "Dutchman's breeches," because the corolla resembles that article of attire. The flowers are cream-colored, tipped with white. Another species is called "squirrel corn," its tubes resembling maize. It has fragrant flowers, of greenish white tinged with red, and is found in rich forest-lands. There are other varieties, but the most beautiful is an importation from Japan, and is popularly known as "the bleeding heart." It has large rosy blossoms, each flower is an inch long, and its blossoming continues for several weeks.

**DICHLAMYDEOUS** (Gr. *dis*, twice, and *chlamys*, a covering), a term in botany, applied to those flowers which have both a calyx and a corolla. Flowers in which the calyx and corolla are very similar, and unite to form a *perianth*, are *dichlamydeous*; as well as those in which they are very different. Decandolle divides dicotyledonous or *exogenous* plants into *dichlamydeous* and *monochlamydeous*; the former including the three sub-classes of *thalamifloræ*, *calycifloræ*, and *corollifloræ*, whilst the latter form a single sub-class.

**DICHOTOMOUS** (Gr., divided into two equal parts), a term often used in botanical description to designate branching by repeated forkings. The veins of the fronds of ferns and of the leaves of some coniferous trees, the stems of some ferns, the fronds of some algae, and the stems of a few phanerogamous plants, are dichotomously branched. The stem of the mistletoe is generally divided in this manner, and it is a remarkable characteristic of that of the doom palm.

**DICHOTOMY**, in anthropology, is the name given to the theory that considers man as having a twofold nature, physical and spiritual, or, in popular language, as body and soul. In this it is opposed to *trichotomy*, which makes a triple division—body, soul, and spirit: giving the name "soul" to all, besides the body, which man has in common with brutes, e.g., certain instincts, affections, and rational faculties; and using "spirit" to designate that in man in which his morality and immortality inhere, and by which he is distinguished from the other animals. See **SOUL**, *ante*.

**DICHROISM** (Gr. *dis*, twice, *chroma*, a color) is a term chiefly used in crystallography to designate the property which many doubly-refracting crystals possess of exhibiting different colors, when viewed in different directions. It, or the allied term *dichromatism*, has also been applied to those fluids which appear of different colors

when viewed by reflected and refracted light; when seen in thick or thin layers, etc. For example, venous blood, or any blood impregnated with carbonic acid, hydrogen, or nitrogen, appears, when seen in moderately thin layers, to be of a purple color; while in extremely thin layers it appears green.

**D'ICHOITE**, or **YOLITE**, a silicate of magnesia, iron, and alumina, found in prisms, and sometimes used as a gem because of its changeable colors.

**DICK**, THOMAS, LL.D., a well-known religious philosopher, was b. in 1774, near Dundee, Scotland, educated at the university of Edinburgh, and intended for the ministry in connection with the Secession church. After a brief pastoral charge, however, he devoted himself to teaching, lecturing, occasional preaching, and authorship. D. proved himself to be a truly useful writer; but although his productions obtained a great popularity both in England and America, they brought him very little pecuniary return. Towards the close of his life, a small pension was granted him in consideration of his literary services. He died at Broughty Ferry, near Dundee, 29th July, 1857, in the 83d year of his age. D.'s principal works are *The Christian Philosopher* (1823); *The Philosophy of Religion* (1825); *The Philosophy of a Future State* (1828); *Celestial Scenery* (1838); *The Sideral Heavens* (1840); and *The Practical Astronomer* (1845). Several of D.'s writings have been translated into other languages; one, even into Chinese.

**DICK BEQUEST**, the name given to a fund bequeathed by James Dick of Finsbury square, London, for the benefit of the parochial school-masters of Moray, Banff, and Aberdeen. Mr. Dick was b. at Forres, Morayshire, in Nov., 1743. Having entered mercantile life in the West Indies at the age of 19, he amassed a considerable fortune, which he subsequently increased in London. He died on the 24th May, 1828, leaving the chief part of his fortune for the purpose above mentioned. The sum bequeathed amounted in 1833 to £113,147 4s. 7d., since increased to £122,000. These funds, being invested in heritable securities, yield (after deducting all expenses) for annual distribution a sum which amounts, on an average, to £4,000. Mr. Dick's object was "to encourage active school-masters, and gradually to elevate the literary character of the parochial school-masters and schools." Acting on this declaration of the testator's wish, the trustees in whom the administration became vested\* ordained first, that with a view to raise the literary character of the school-masters, none should, after a certain date, participate in the bequest who had not passed, to the satisfaction of examiners appointed by them, an examination in the English language and literature, geography, arithmetic, geometry and trigonometry, algebra to quadratic equations inclusive, Latin, Greek, history, and chronology. To these branches have lately been added an examination in the art of teaching and in physics. To those who highly distinguish themselves in these examinations, a sum of money is awarded by the trustees, and they are entitled to a small allowance during their term of office. Further, with a view to raise the literary character of the schools, and to encourage active school-masters, the trustees appointed a visitor, who should report annually to them on the condition of the schools, making a round of all those schools, whose teachers claim participation, once in three years—now, once in two years.

In allocating the fund at their disposal, the trustees take into consideration the number of scholars attending each school, the branches taught, the fees paid, and the salary fixed by the school-board. Each of these elements has attached to it a certain value, the object of this being to make it the interest of teachers and school-boards to promote the education of the parish. The sum to which a teacher may be entitled in consequence of the position he holds on the books of the trustees in the above respects, is allowed, increased, restricted, or refused, according to the report of the visitor on the condition of the school. The highest sum paid to any teacher in 1877, for example, was £59 8s. 5d.; the smallest, £18; the average about £30. A small proportion of teachers do not participate in consequence of their having failed to comply with the conditions of the trustees.

There can be no doubt that the operation of this bequest has been most advantageous. There is no district in Scotland in which the parochial schools are so uniformly taught by highly qualified men; the results of the teaching, it would not probably be easy to equal anywhere. The rights of the teachers of these schools, and of their successors, to participate in the bequest, are not prejudiced by the education act of 1872.

**DICKENS**, CHARLES, novelist and humorist, was b. at Landport, in Hampshire, in Feb., 1812. His father, Mr. John Dickens, was employed for some years in the navy pay department, but at the conclusion of the war with France was pensioned, and became a parliamentary reporter. In this pursuit his son was soon distinguished for uncommon ability; and after a literary engagement—at a very early age—upon *The True Sun*, he attached himself to the staff of the *Morning Chronicle*. In this newspaper he gave the first evidence of his talents in the lively essays, entitled *Sketches by Boz*, published in 1836. Encouraged by their success, he undertook to write the letter-press of the *Adventures of Mr. Pickwick*, the illustrations of which were to be executed by the then more famous Mr. Seymour, a comic draughtsman. The result was as though Shakespeare

\* The keeper and deputy-keeper of the signet (Edinburgh), the treasurer of the society of writers to the signet, and eight commissioners chosen by and from among the commissioners of the signet.

had been engaged to write the libretto for an opera of Mr. Balfe's. *The Pickwick Papers*, which had an enormous commercial success, commenced also an era in English literature. It was the first of a series of fictitious works exhibiting the life and manners of the middle and lower classes, which, up to that time had had scarcely any exponent. In one respect, however, this book had neither predecessor nor progeny. Neither before nor since has there ever been such a literary embodiment of healthy animal spirits. There is none like it for unflagging but never unwise merriment—for humor that is very much the reverse of dry. That Mr. D. gave us no more *Pickwick Papers* is to be lamented, but may be easily explained by the fact, that he never had the advantage of being five-and-twenty again. Since then, however, he has given us many works more admirable in other respects. *Nicholas Nickleby*, his next effort, was, as a story, greatly in advance of it. It was also the first of those social novels which form so marked a feature in modern literature. It was aimed at the wrongs and cruelties inflicted upon their wretched pupils by the cheap schoolmasters of Yorkshire—and it hit its mark. After this beginning, our author set lance in rest against many a social monster. He may be sometimes wrong, but he can scarcely be accused of want of honesty of purpose; while quite as little can partisanship (except that he is always for the poor) be laid to his charge, since at the very time that the country gentlemen were shaking their heads at him for his want of reverence for "land," he incensed the manufacturing interest by the publication of *Hard Times*. His sarcasm is of a rather peculiar character; too good-natured to sneer, and with eyes, notwithstanding their indignant fire, that never lose sight of the ludicrous side of things, his style is mocking argument. After *Nicholas Nickleby* came *Master Humphrey's Clock*, containing the *Old Curiosity Shop* and *Barnaby Rudge*. In the former of these, and in the character of Little Nelly, he first exhibited that power of setting forth child-life and child-thought which may have been said perhaps, before the publication of George Eliot's works, to be peculiarly his own. *Barnaby Rudge* was his first, and, with the exception of his subsequent *Tale of Two Cities*, his only attempt to describe the past; and it was a successful one. It is probably, with reference to plot and circumstance, his best novel, barring *David Copperfield*. The *Old Curiosity Shop* began in a curious dreamy manner, which, although obviously a favorite one with our author, he soon perceived was unappreciated, and had the prudence to discontinue. This disposition of his mind towards the weird and the grotesque he subsequently developed with greater success in his *Christmas Stories*. After a voyage across the Atlantic, Mr. D. published, in 1843, his *American Notes for General Circulation*; but a much more admirable result of that expedition appeared in his *Martin Chuzzlewit*. This was certainly the greatest of his humorous works since the *Pickwick Papers*, and it may almost be said to have been his last. From this period, his animal spirits—a rare gift among even comic authors, and rarely lasting so long as in his own case—appeared to have deserted him. His humor, except in some rich creations, such as Mr. Micawber, was no longer so apparent, while, on the other hand, his wit and pathos increased. *Dombey and Son* was considered a falling off in one who stood so high; but his death of little Dombey brought tears to the eyes of lawyers. When men were expecting that he should wane and weaken like other prolific writers before him, he produced a novel as fresh as the dawn. In this, he, for the first time, adopted the autobiographical form, and that perhaps offered him some advantages; but at all events, the result was admirable. *David Copperfield* is, in our judgment, by far his greatest work, and will endure—though for very different reasons—as long as the *Pickwick Papers*. Its Agnes is one of the most charming female characters in the whole range of fiction. *Bleak House*, *Hard Times*, *Little Dorrit*, the *Tale of Two Cities*, *Great Expectations*, and *Our Mutual Friend*, afterwards succeeded one another with almost periodical punctuality, and an audience larger than any English author ever had awaited each. We must also note *Oliver Twist*, one of his most popular works, the first installment of which appeared in 1837 in *Bentley's Miscellany*. No prose-writer was ever more quotable or more quoted than he. In 1845, the *Daily News* was started under Mr. D.'s editorial auspices, but the task appears to have been ungenial, for he soon withdrew from it. In 1850, he commenced a weekly periodical entitled *Household Words*, afterwards merged in *All the Year Round*. In 1867, he again visited America, giving numerous readings, and meeting with a brilliant reception. He was till the last engaged in writing a new novel, *The Mystery of Edwin Drood*, which was left unfinished. He died on June 9, 1870. His *Life* was written by John Forster (3 vols. 1871-74).

DICKINS, ASBURY, 1773-1861; son of John, the Methodist minister. In 1801, he was associated with Joseph Dennie in the *Portfolio*, a weekly publication. He spent some years in Europe, and on return was given a place in the treasury department, and afterwards in the state department, where he was acting secretary. In 1836, he was chosen secretary of the United States senate, and filled the office 25 years, until his death.

DICKINS, JOHN, 1747-98; a native of London, educated at Eton. He came to America before the revolution, and was one of the most zealous and efficient promoters of the Methodist Episcopal church in the country. He preached in Virginia and North Carolina, and in 1783, took charge of the John-street church in New York city. In 1789,

he was stationed in Philadelphia, and there established the "Methodist Book Concern," afterwards removed to New York.

DICKINSON, a co. in n.w. Iowa, on the Minnesota border; 430 sq.m.; pop. 75. 1748. Spirit lake occupies a considerable part of its area. Agriculture is the principal business. Co. seat, Spirit Lake.

DICKINSON, a co. in central Kansas, on the Kansas river, crossed by the Kansas Pacific railroad; 846 sq.m.; pop. 78, 10,856. The surface is chiefly prairie and fertile, producing wheat, corn, oats, etc. Co. seat, Abilene.

DICKINSON, ANNA ELIZABETH, b. Philadelphia, 1842. Her father died when she was but two years old, and she received a rudimentary education in a Quaker school. When but 14, she wrote for the *Liberator* an article on "Slavery." At 17, she taught school in Bucks county. The next year she made her first speech at a meeting of Progressive Friends (Quakers) in Philadelphia, her subject being "Woman's Rights and Wrongs," and thenceforward she was a frequent speaker, chiefly on total abstinence and slavery. Near the close of 1861, she added politics, and strongly supported the war for the union. Of late years she has devoted her attention to lecturing and to the drama, writing *A Crown of Thorns*, and *True to Herself*, and acting in these plays with moderate success.

DICKINSON, JOHN, LL.D., 1732-1808; b. Md., educated in London, a lawyer in Philadelphia; deputy to the first colonial congress, and a member of the continental congress of 1774, to which body he presented several important papers. He spoke against the declaration of independence, deeming it premature, and was one of the few members who did not sign that document. He was representative from Delaware in congress in 1779. In 1783, he founded Dickinson college, Carlisle, Penn., to which he gave a liberal endowment.

DICKINSON, JONATHAN, 1688-1747; b. Mass.; graduate of Yale. He was for 30 years a Presbyterian minister in Elizabethtown, N. J., and was in high repute in all the region. In 1746, he was elected president of the college of New Jersey. He wrote a number of theological works.

DICKINSON COLLEGE, at Carlisle, Pa., was established as a Presbyterian institute, 1783, but passed under Methodist control in 1833. It was named for John Dickinson, one of its principal founders. It has a productive endowment of about \$215,000, with an annual income of from \$14,000 to \$15,000. The campus embraces about nine acres, with a beautiful growth of trees. The buildings, three in number, are of stone, substantial, commodious, and well adapted to their purposes. The apparatus for illustration in scientific studies is valuable, and annually increasing. The astronomical observatory is provided with an achromatic telescope, having an object-glass of five inches, and a focal distance of seven feet, equatorially mounted, and furnished with right ascension and declination circles. There is a museum of natural history and geology, and a library of 28,458 volumes. The old classical curriculum is maintained, with allowed divergencies in junior and senior years in favor of scientific and theological students. All the students physically competent are under military instructions and drill. There is a preparatory school under the immediate control of the faculty. The number of professors (1880) is 12; of the students, 120. President, J. A. McCauley, D.D. Among the eminent alumni may be mentioned president Buchanan, chief-justice Taney, and postmaster-general Creswell.

DICKSON, a co. in n. Tennessee, on the Cumberland river and its affluents, intersected by the Nashville and Northwestern railroad; 650 sq.m.; pop. 70, 9,340-1677 colored. It has a rolling surface and fertile soil. The Cumberland river is navigable for steamboats. The productions are corn, tobacco, etc. Co. seat, Charlotte.

DICKSON, SAMUEL HENRY, LL.D., 1798-1872; a physician, b. S. C.; graduate of Yale, 1814; studied medicine in the university of Pennsylvania. In 1824, he was appointed to the professorship of the institutes and practice of medicine in the medical college of Charleston. In 1847, he was professor of the practice of medicine in the university of New York. In 1858, he accepted a similar chair in the medical college in Philadelphia. He published many volumes and papers on medical subjects.

DICLINOUS (Gr. *dis*, twice, and *klinē*, a bed), a term in botany, signifying that flowers are unisexual, having stamens only, or pistils only, and opposed to *monoctinous* or *hermaphrodite*. It is much used by some botanical authors.

DICOTYLEDONOUS PLANTS are those of which the embryo is ordinarily furnished with two seed-lobes or cotyledons (q.v.) opposite to one another, or with more than two, which in that case are verticillate. In general there are only two cotyledons; a greater number being of rare occurrence, but being found in some of the *coniferæ*, as spruce-fir, larch, etc., in *ceratophyllum*, etc. It is not, however, always quite easy to determine whether a plant belongs to the class of dicotyledonous plants or to that of monocotyledonous plants (q.v.), as sometimes, in the former, only a single cotyledon presents itself, which is the case with a number of species of the sub-genus *bulbocapnos* in the genus *corydalis*; or the cotyledons are altogether wanting, as in dodder (*cuscuta*), or the embryo is in so rudimentary a state in the seed, that it at first consists only

of a pair of cells as in *monotropæa*. The habit of the plants is therefore also to be taken into account, and particularly the structure of the stem and its mode of increase. The *radicle* of the embryo in dicotyledonous plants generally elongates itself by degrees until it forms the root of the plant itself; wherefore Richard designated these plants *exorhizæ* (Gr. *exo*, outward, and *rhiza*, a root). The stem is exogenous (q.v.), and usually branched. The leaves have branching veins, and exhibit great variety of form. They are articulated to the stem. The calyx and corolla, when both present, are usually more distinct and dissimilar than in monocotyledonous plants.

**DICOTYLES.** See PECCARY.

**DI CRANUM**, a genus of mosses, having a single *peristome* of sixteen equidistant bifid teeth and the *calyptra* splitting up on one side (*dimidiate*). See MOSSES. The species are numerous, and some of them are among the most common British mosses, growing on the ground and on moist rocks. Many of them have elongated branching stems.

**DICTA TOR**, in the earliest times, was the name of the highest magistrate of the Latin confederation, and in some of the Latin towns the title was continued long after these towns were subjected to the dominion of Rome. In the Roman republic the D. was an extraordinary magistrate, irresponsible and endowed with absolute authority, whose original name was *magister populi*. The frequency of *crises*, or critical periods, in the quick, aggressive growth of the Roman state, necessitated such an office. The first D. (T. Læcius or M. Valerius) was appointed 501 B.C., nine years after the expulsion of the Tarquins. According to Livy, the immediate cause of this dictatorship was a formidable war with the Latins. In general no one could be appointed D. who had not been previously consul, and this condition was very rarely dispensed with. Niebuhr is of opinion that the D. was originally created or elected by the *curiæ*, like the kings, but it is more probable that the senate passed a decree ordering one of the consuls to name or proclaim (*dicere*) a dictator. Originally, of course, the D. was a patrician; the first plebeian who filled the office being C. Marcus Rutilus, 356 B.C., who was nominated by the plebeian consul M. Popillius Lænas. The dictatorship could not *lawfully* be held longer than six months, nor was it ever so, except in the cases of Sulla and Cæsar, which were altogether peculiar. It must not be supposed that during a dictatorship the functions of the other magistrates were positively suspended. The consuls and other regular authorities continued to discharge their proper duties, but in subordination to the direction and command of the D.; being for the time simply his officers. The superiority of his power, when compared with that of the consuls, appears chiefly in these three points: he was far more independent of the senate; he had a more extensive power of punishment, without any appeal; and he could not be called to account after his abdication of the dictatorship for anything he had done during the period of his office. The *limits* of his power were as follows: he could not touch the treasury; he could not leave Italy; and he could not ride through Rome on horseback without previously obtaining the permission of the people. While the consuls had only 12 lictors, the D. was preceded by 24, bearing the *secures* and *fusces*. To him also belonged the *sella curulis* and the  *toga prætexta*. The last legally elected D. was M. Junius Pera, who entered on his office 216 B.C. From this time *nominal* dictators were frequently appointed for the purpose of holding the elections, but even these finally disappeared, 202 B.C. Henceforth, in critical times, a sort of dictatorial power was conferred on the consuls by the senate by the well-known formula: "That the consuls should see to it, that the state should receive no damage." This practice rendered the appointment of *dictators* no longer necessary.

**DICTIONARY**, is merely the English form of *dictionary*, a word not to be found in classical Latin, though of frequent use in that called monkish or mediæval. A D. is, as every one knows, a book, but, in the widest sense of the word, its contents admit of no more strict definition than that they are arranged according to the order of the alphabet, and that every word within the scope professed to be embraced by the D. must have its proper place accordingly. It may be further said that the D., in order to distinguish it from a mere list or index, must contain explanations or information about each word thus included within its scope, except in cases, of which many examples may be found in the present work, where it is sufficient to refer for a part or the whole of the account of one word to what is said under some other word. There are several other terms that are used synonymously, or nearly so, with dictionary. The Greek word *lexicon* is in common use for a D. of languages. It is not entirely so limited, however, in practice, as may be seen in such works as the *Lexicon Juridicum* of Calvinus or Kahl, which is just a D. of Roman and feudal law, of the same kind as sir Edward Tomlin's *Law Dictionary* is of English law. The word encyclopædia has generally a wider meaning; but there are often several books exactly of the same kind, of which some are called dictionaries, and others encyclopædias. Glossary and vocabulary are nearly synonymous with a D. of a language; and the words thesaurus, catalogue, directory, gazetteer, and index, are sometimes used as a title when D. might be not inapplicable.

Dictionaries may be divided into two classes—(1) dictionaries whose object is to explain words and phrases; and (2) those that aim at giving information about things.

1. Dictionaries of language are, again, divided into various sub-classes or species. The most common kind—what, indeed, is understood by the term D. (and the equiva-

lent Greek term *lexicon*) when used by itself—is an alphabetical list of the words composing any language, either explained in the same language, or interpreted by the corresponding words of one or more other languages. To indicate that all, or nearly all, the words of the language are embraced, the name *thesaurus* (treasury) is sometimes used. *Special* dictionaries contain only the words used by single authors, or classes of authors. A *glossary* is a D. of unusual terms. An *etymological* D. is one in which the derivation of words is the sole or a prominent object.

2. Dictionaries of things (Ger. *realwörterbücher*), or of information, are also of various kinds. When the whole field of human knowledge is embraced, we have an alphabetical encyclopædia. The name encyclopædia or cyclopædia is sometimes given to dictionaries of special departments of knowledge, as the *Cyclopædia of Anatomy and Physiology*; but in all such cases, D. seems the correcter term. See *ENCYCLOPÆDIA*.

There is no kind of information, within wide or narrow bounds, that may not be thrown into the D. form. Dictionaries of apt quotations from the classics, the Scriptures, or the fathers, were much in vogue in the 17th century. There are dictionaries of biography, of geography, of dates, of architecture, of cookery, of political economy, of fortification—in fact, of every object of human knowledge and practice. As dictionaries of this class are of the same nature, except as to the restriction of their field, as encyclopædias properly so called, we reserve some notice of the more important of them for that head.

Dictionaries of language, in our sense of the word, are of modern origin. The Greeks and Romans had no idea of a book embracing all the words of their own or any foreign tongue. Glossaries, however, of unusual words and phrases were early current. The earliest work of the kind extant (though much interpolated) is the Homeric lexicon (Gr. *Lexis Homeriké*, “Homeric words”) of Apollonius, an Alexandrine grammarian of the time of Augustus. More extensive compilations, such as the lexicon of Suidas (q.v.), and the *Etymologicum Magnum* (q.v.), were made in the middle ages. A real D. became first possible after the invention of printing. A broad and sure basis for Greek lexicography was laid by Henry Stephens (q.v.) in his *Thesaurus* (1572); the Latin *Thesaurus* of Robert Stephens, which did the same for Latin, had appeared in 1531. Previously to the discovery of printing, and for some time after, the explanations of Latin words were given in Latin. “The earliest printed vocabulary with which we are acquainted in which the words of any modern language answering to the Latin are inserted, is the *Promptorium Puerorum*, published by Pynson in 1499, in which English words are followed by their supposed Latin equivalents” (*Quarterly Review*, Sept., 1855). Some of the more important dictionaries will be noticed under the heads of the several languages.

**DICTUM DE KENILWORTH** was an edict or award between king Henry III. and all those barons and others who had been in arms against him, and so called because it was made at Kenilworth castle, An. 5 Henry III., containing a composition of five years' rent for the lands and estates of those who had forfeited them in the rebellion.—*Cowell's Interpreter*.

**DICTY OGENS**, in botany, a class established by Lindley for the reception of a comparatively small number of natural orders, genera, and species, usually included by other botanists among *endogens* or endogenous plants (q.v.), but which, whilst they agree with endogens in the structure of the embryo, differ from them in the stem and leaves. The annual branches or aerial stems have indeed the endogenous structure, but the rhizomes or subterranean stems more resemble the structure of exogenous plants (q.v.), with pith, medullary rays, and wedge-like vascular bundles. The leaves are broad and net-veined, usually disarticulating with the stem. The most important natural orders referred by Lindley to this class are *dioscoreaceæ* and *smilacææ*, and the most important plants belonging to it are the different species of yam and sarsaparilla.

**DICTYS of CRETE**, one of the early historians from whom certain Roman writers imagined that Homer derived material for the *Iliad* and the *Odyssey*. According to an introduction prefixed by an unknown writer to the Latin translation entitled *Dictys Cretensis de Bello Trojano*, the author followed Idomeneus, king of Crete, in the Trojan war; the manuscript of his work, written in Phœnician characters, was found in his tomb at Gnosus at the time of an earthquake in the 13th year of Nero's reign, and translated into Greek by Nero's order. A Latin version of the first five books is all that has come down to us; but this is generally regarded as a forgery. The main interest of the work consists in the fact that, with the work of Dares, it was the medium through which Homeric legends were introduced into the literature of the middle ages. (From *Encyclopædia Britannica*.)

**DICY NODON**, the name given by Owen to a genus of fossil reptiles, whose remains have been found in South Africa. The true age of the rock in which they occur has not been ascertained; the accompanying organisms seem to indicate that it is triassic. Few bones of these animals, save those of the skull, have been sent to this country. A complete restoration of one would be a most valuable addition, not only to paleontology, but to systematic zoology as well; for the numerous skulls that have been examined, have been sufficient to show that this is one of those anomalous forms which unite in their structure the characteristics of widely different animals. It has affinities with the

crocodile, the lizard, and the tortoise, though perhaps the completely closed orbits and the sharp compressed jaws ally it more closely to the last-named animal. Its lower jaw also is covered with a horny plate, as in the tortoise. The most remarkable peculiarity is the existence of a pair of large sharp-pointed tusks, one from each side of the upper jaw, growing downwards as in the mammalian morse or walrus. The generic name, meaning "two canine teeth," has been given to them from these singular tusks, which are peculiar to this genus. The articulating surfaces of the vertebræ are both hollow—a fish-like peculiarity, from which it might be argued that these reptiles were good swimmers; probably they lived constantly in the water, but the construction of the bony passages of the nostrils proves that they must have come to the surface to breathe air. Four species have been discovered.

**DIDACTIC POETRY**, that kind of poetry which aims, or seems to aim, at instruction as its object, making pleasure entirely subservient to this. It has been disputed whether or not the existence of a kind of poetry especially entitled to the name didactic, consists with the very nature and object of the poetic art. For it is held that, to point out instruction as the peculiar object of one kind of poetry, is to overlook the high aim of all poetry; and that a poem may be in the highest sense didactic, which yet is epic, dramatic, or lyric in its form; and the book of Job, the Psalms, and other poems contained in the Sacred Scriptures, are quoted as examples. In the poems generally called didactic, the information or instruction given in verse is accompanied with poetic reflections, illustrations, episodes, etc. The *Georgics* of Virgil have been the model according to which didactic poems have very generally been composed; and the literature of all European nations contains many productions of this kind; whilst no subject is so unpromising that it has not found some one to select it as a poetic theme.

**DIDELPHIS.** See OPOSSUM.

**DIDEROT, DENIS**, a celebrated French encyclopedist and philosophical writer, was born at Langres, in Champagne, 5th Oct., 1713. He was educated for the church at the college of his native town, and subsequently at that of D'Harcourt, Paris; but disliking the clerical office, and after having made a trial of law, a profession which he also found uncongenial, he finally resolved, after various vicissitudes, upon becoming a *littérateur*. For some years, however, his mode of life was very precarious. On one occasion, being reduced to the greatest extremities, he seriously resolved that if the world should ever prosper with him, he, not ignorant of misfortune, would never disregard the applications of the indigent. This resolution was religiously kept; for after having attained a position of comparative affluence, he was continually surrounded by applicants desirous of obtaining assistance, which, whether in the shape of money or instruction, D. was always willing to afford them. Although very poor, D. married in 1743. Necessity now drove him to increased exertions. He translated the *History of Greece* from the English of Stanyan, receiving for this work the sum of 100 crowns. Soon afterwards followed the *Essai sur le Mérite et la Vertu*; the *Pensées Philosophiques*, written, it is said, in the space of four days; and the *Interprétation de la Nature*. Shortly after appeared his *Lettre sur les Aveugles*, for the writing of which he was confined three months in the prison of Vincennes. Believing that it was, among other things, his vocation to regenerate the theater, he produced a melodrama (1758), entitled *Le Père de Famille*. It was unsuccessful, and was followed by others equally so, so that it was said, "Le Père de Famille a été le père d'une famille déplorable."

But D.'s great work was the *Encyclopédie*, of which he and D'Alembert were the joint editors. It was commenced in 1749. D., besides revising all the articles, wrote the departments of history, of ancient philosophy, and of the mechanical arts. He also wrote art criticisms from 1765 to 1767, showing a readiness in interpreting the meaning of a picture, and a power in reproducing it vividly in words, unequalled by any writer of his time. Towards the latter portion of his life, D., who had never been able to save any money, determined to sell his library, to provide for his only daughter. The empress Catherine of Russia, having been informed by her French ambassador of his intention, bought the library, on condition that D. himself should be librarian, and undertake the care of it at a salary of 1000 francs yearly. In 1778, he set out for St. Petersburg to thank his imperial benefactress, returning in the following year. But his health, which was impaired by this journey, soon after gave way, and he died on the 30th July, 1784.

D. had worked at the encyclopædia for the space of about 30 years. His fitness, natural and acquired, for this species of literary labor was complete. With the advantage of an excellent education, he had a great love of truth, and a curiosity to ascertain the real relations of any subject upon which he was engaged. He was distinguished by a swiftness and dexterity of intellect, that enabled him to catch the salient points of his topic, and to present them in the best light. As regards religion, D. was an atheist, sincere even to fanaticism in his opinions, and anxious to indoctrinate his countrymen with his own skepticism. The *encyclopédie* became a vehicle for the indirect propagation of his views. One of the last recorded sayings of D. is very characteristic: "The first step towards philosophy is incredulity;" but, unfortunately, D. thought it was also the last. An edition, in 20 vols., of all D.'s works, by Assézat and Tournoux, was com-

pleted in 1877. See John Morley's monograph on *Diderot and the Encyclopædists* (3 vols., 1878).

**DIDIUS SALVIUS JULIANUS, MARCUS**, for a brief period emperor of Rome, under the name of Marcus Didius Commodus Severus Julianus. He was quæstor, ædile, and prætor; commanded a legion in Germany, and was governor of Belgic Gaul, and afterwards of Dalmatia and lower Germany. He was consul and proconsul in Africa, and governor of Bythinia in Asia Minor. When Pertinax was assassinated, the throne was offered to the highest bidder by the prætorians, and Didius bought it, thus becoming emperor; but whenever he appeared in the streets he was greeted with the epithets of "robber" and "parricide." The legions abroad did not recognize him, and proclaimed Septimus Severus as the true emperor. Severus marched to Rome and was recognized by the senate. Didius was deserted, and after two months' reign was killed by a soldier.

**DIDO**, or **ELISSA**, according to the legend, the foundress of Carthage, was the daughter of a king of Tyre, called by some Agenor or Belus, by others Mutgo or Matgenus. His successor, Pygmalion, the brother of D., murdered her husband and uncle, a priest of Hercules named Acerbas; by Virgil, Sichæus. With the treasures of Sichæus, which Pygmalion had sought for in vain, and accompanied by many Tyrians, D. escaped to sea. She landed in Africa, not far from the Phœnician colony of Utica, and built a citadel called Byrsa (from Gr. *Bursa*, the hide of a bull), on a piece of ground which she had bought from the Numidian king Iarbas. The meaning of the word Byrsa, gave rise to the legend that D. purchased as much land as could be encompassed with a bullock's hide. After the agreement she cut the hide into small thongs, and thus inclosed a large piece of territory. Here she built the city of Carthage. To avoid being compelled to marry Iarbas, she stabbed herself on a funeral pile, which she had caused to be erected, and after her death was honored as a deity by her subjects. Virgil ascribes the death of D. to her unrequited passion for Aeneas; but many of the ancient writers conceived that the poet had committed an anachronism in making her contemporary with the Trojan prince. The more general opinion was, that D. had built Carthage somewhere between 50 and 100 years before the foundation of Rome.

**DIDOT**, the name of a celebrated family of French printers and publishers.

**D., FRANÇOIS**, the first of the family that attained eminence, was b. in 1689, and d. in 1757. His principal professional achievement was the publication of the *Voyages* of his friend the abbé Prévost, a work in 20 volumes, perfect as regards the text, and enriched with a great number of engravings and geographical maps. D. had eleven children, of whom two—**FRANÇOIS AMBROISE D.** (b. 1730, d. 1804) and **PIERRE FRANÇOIS D.** (b. 1732, d. 1795)—acquired considerable distinction as printers. **HENRI D.** (b. 1765, d. 1832), eldest son of Pierre François, made himself famous as an engraver, letter-founder, and mechanician. He was 66 years old when he engraved, for his well-known "microscopic" editions of eminent authors, those characters which are the *ne plus ultra* of typographical art. A daughter of the third son of Pierre François married Bernardin de Saint Pierre, who was for some time associated with the Didots in their paper manufactory of Essonne; and in his country-house near this place wrote his *Paul et Virginie*. **PIERRE D.**, eldest son of François Ambroise (b. 1760, d. 1853), still further increased the fame of the family. His Louvre editions of *Virgil*, *Horace*, *Racine*, and *La Fontaine* are magnificent. At the exhibition of the products of industry in 1801, a jury declared his *Racine* to be "la plus parfaite production typographique de tous les âges." Besides a great number of works, not less remarkable for their typographical perfection than for their literary value, such as the *Voyages de Denon*, D. published a collection of the French *chefs-d'œuvre*, dedicated *Aux amis de l'Art Typographique*. D. was also an able littérateur.

**D., FIRMIN**, brother of the preceding, and son of François Ambroise D., was b. at Paris in 1764. As a printer, and especially as an engraver and founder, he raised the family name to the pinnacle of professional eminence. The absolutely perfect Roman characters used in the Louvre editions printed by his elder brother, were engraved and cast by him. Firmin D. applied the stereotyping process to the *Logarithmic Tables* of Callet, a work that required to be executed with the most rigorous accuracy, and which, through this means, is perfectly free from error or blemish. The whole of the French, as well as most of the Italian and English classics, were published by him according to the same process. These stereotypic editions (the word *stereotype* was invented by Firmin D.) were wonderfully correct and cheap; *Virgile* is without a blemish, is ornamented with vignettes, and was sold for 15 sous (7½d.); it was a kind of revolution in the book-trade of France. The most distinguished foreigners were accustomed to visit D.'s establishment as one of the great sights of Paris. The emperor Alexander, when in Paris in 1814, minutely examined every department of it; and placed under D. two young Russians, to be instructed in all the branches of typography. Some of the most celebrated continental printers served their apprenticeship with him. In 1827, Firmin D. retired from business, to devote himself wholly to his duties as *député*. A sage friend of freedom, he attached himself to the moderate and constitutional opposition, headed by Royer Collard. D. also obtained considerable reputation as an author by his tragedies, *La Reine de Portugal* and *La Mort d'Annibal*, and several volumes of metrical translations from the classics. He died 24th April, 1836.

**D., AMBROISE FIRMIN, and HYACINTHE**, sons of the preceding, b. 20th Dec., 1790, and 11th Mar., 1794, long carried on the family business (aided by their sons, **ALFRED** and **PAUL D.**), under the firm of Firmin Didot, Frères. Ambroise died in Feb., 1876; but in the hands of the survivors, the business still retains its magnitude.

**DIDRON, ADOLPHE NAPOLEON**, 1806-67; a French archæologist. By the advice of Victor Hugo he turned his attention to Christian archæology, and examined nearly all the old church edifices of France. In 1839, he went to Greece to study the eastern churches. In 1844, he started a periodical, *Annals of Archæology*, devoted to his favorite subject, and was the editor until his death. In 1845, he established in Paris a special archæological library, and at the same time a manufactory of painted glass. In the same year he became a member of the legion of honor. His most important work is *Christian Iconography*.

**DIDYMIUM** is a very rare metal found in the minerals CERITE, ALLANITE, etc.

**DIDYMUS, OF ALEXANDRIA**, 309-394; an ecclesiastical writer. Although he became blind at the age of four, before he had learned to read, he succeeded in mastering all the sciences then known, and on entering the church was placed at the head of the Alexandrian school of theology. Most of his works are lost, but we possess a translation by Jerome (one of his pupils) of his treatise on the Holy Ghost, and a translation by Epiphanius of his comments on the canonical epistles. A treatise against the Manichæans in Greek is also extant.

**DIE, ST.**, a t. of France, in the department of Vosges, is situated on the Meurthe, 25 m. n.e. of Epinal. It is handsomely built; its streets clean and regular. D. is also the seat of a bishop, has an old cathedral church, and various important educational institutions. It has manufactures of cotton goods, with some trade in corn, cattle, flax, hemp, paper, ironmongery, etc. There are copper and iron mines, ironworks, and marble quarries in the neighborhood. Pop. '72, 9,454.

**DIEBITSCH-SABALKANSKI, HANS KARL FRIEDRICH ANTON**, Count, 1785-1831; Count von Diebitsch and Narden, a Russian field-marshal, native of Silesia. At the age of 12 he entered the Prussian army, but left it four years later for the Russian service. He was wounded at Austerlitz, fought at Eylau and Friedland, being promoted to captain after the Friedland conflict. In 1812, he distinguished himself by the re-capture of Polozk, and by a defense which saved Witgenstein's corps, which was then in retreat. He was made maj.gen., and with gen. Yorek took possession of Berlin. After the battle of Lutzen he was sent to Silesia, and had a share in negotiating the secret treaty of Reichenbach. After the battle of Leipsic, he was made lieut.gen. In 1814, he urged the march of the allies on Paris, for which the emperor conferred on him the order of St. Alexander Newski. In 1815, he married, attended the congress of Vienna, and was made adjt.gen. to the emperor. He was present at Alexander's death at Taganrog. The emperor Nicholas made him baron and count. In the Turkish war, 1828, he had the chief command, took Varna, crossed the Balkans, and made peace at Adrianople. The crossing of the Balkan mountains was commemorated in the addition of *Subalkanski* to his name, and his elevation to the rank of field-marshal. On the outbreak in Poland in 1830, he was given the chief command. He died of cholera in June of the next year.

**DIEDENHOFEN**, called by the French Thionville, a t. in Germany on the Moselle, and the railroad from Metz to Luxemburg, 15 m. n. of Metz; pop. '71, 7,155. It has a botanic garden, a gymnasium, and many manufactories. The Carlovingian rulers some times resided here. Subsequently it belonged successively to Luxemburg, Burgundy, Austria, and Spain. In 1643, it was annexed to France. In 1870, it was taken by the Germans, and by the treaty of 1871, was annexed to Germany.

**DIEFFENBACH, JOH. FRIED.**, a celebrated surgeon of recent times, was b. in Königsberg in Prussia, in 1792. He had begun the study of theology when the war of liberation broke out, in which he took part as a volunteer. In 1816, he exchanged the study of theology for that of medicine, and especially surgery. After studying at Bonn and elsewhere, and traveling in France, he took his degree in 1822, and commenced practice in Berlin, where he soon attained distinction as an operator, and in 1840 was promoted to be professor and director of clinical surgery. He died in 1847. Besides eminent skill in all the usual operations with the knife, D. introduced many improvements, particularly in the art of forming new noses, lips, eyelids, and the like, as well as in cutting the muscles for squinting and stammering. Of his writings, we may mention *Die Transfusion des Bluts und die Einspritzung der Arzneien in die Adern* (Berl. 1828), *Ueber die Durchschneidung der Sehnen und Muskeln* (Berl. 1841); *Die Heilung des Stotterns* (Berl. 1841); *Die Operative Chirurgie* (12 vols., Leip. 1844-48), his chief work, which has been translated into several languages.

**DIEGO, SAN**, the best harbor in upper or American California, next to that of San Francisco, is in lat. 32° 45' n., and long. 117° 8' west. It is 6 m. long, and varies in breadth from 1 to 2; and it is 6 or 7 fathoms deep, even to the shore. The climate is singularly equable and salubrious. The exports of D. consist mainly of gold bullion, wool, wheat, flour, barley, hides, honey, wine, and olive oil; and in 1874 had a value of nearly £500,000. The town has two daily papers and two weeklies. Pop. '70, 2,300.

North San D., a hamlet 4 m. to the n. of the city, was the first place in California settled by white men.

**DIELY TRA**, a genus of plants of the natural order *fumariaceæ*, in appearance and habit much resembling fumitories of extraordinary size. *D. spectabilis*, a native of Siberia and the northern provinces of China, was introduced into Britain from the island of Chusan in 1846, and rapidly became a general favorite, on account of its long racemes of drooping, delicate, rosy-pink flowers. It is now to be seen not only in greenhouses, but, as commonly as almost any flower, in cottage-windows, and even in cottage-gardens, although in the northern parts of Britain it seldom attains its full luxuriance in the open air. It is one of the favorite plants of the Chinese.

**DIEPENBECK**, ABRAHAM VAN, a distinguished Flemish painter, was b. probably in 1607, at Hertogenbosch (Bois-le-Duc), and at first confined himself to painting on glass, in which he acquired the reputation of being the first of his time; but having conceived a disgust for this kind of painting, on account of the cracking of the glass, which he could in no way prevent, he abandoned it, and became a pupil of Rubens. He then went to Rome, and on his return to Belgium became a sort of assistant to his master. In 1641, he was elected president of the Antwerp academy, an honor which he retained till his death, in 1675. D. painted much, and with wonderful facility, on tapestry and wainscoting. He certainly imitated Rubens, but with great freedom and force of coloring. His works consist, for the most part, of designs for title-pages, theses, devotional subjects, and the decoration of books. They exhibit great fertility and liveliness of genius, but are in general hurriedly and imperfectly finished. His masterpiece in this way is the *Tableau du Temple des Muses* (Paris, 1655), a series of designs, 59 in number, engraved by the best artists of the time—Bloemart, Malmstram, etc. Those of Bellerophon, Orpheus, the Dioscuri, Leander, etc., have been pronounced unsurpassed. His oil-paintings on canvas are few, but the churches of Antwerp have many windows painted by him. D. resided in England for some time during the reign of Charles I., and painted several landscapes and animals for William Cavendish, duke of Newcastle.

**DIEPPE**, a seaport t. of France, in the department of Seine-Inférieure, at the mouth of the river Arques, on the English channel, lat. 49° 55', long. 1° 5' e. D. is situated between two high ranges of chalk cliffs, is regularly built, with tolerably wide, clean streets running parallel to the sea; and the houses—built for the most part of stone and brick, with high slanting roofs—have a picturesque appearance. It is walled, has a castle occupying a high cliff at the w. end of the town, which it commands, as well as the harbor, which is situated to the n.e., and admits vessels of 500 tons burden. West of the old castle lies the little fishing suburb of Pollet, far from beautiful in appearance, but exceedingly interesting from the fact that the inhabitants differ in language, manners, and costume from the rest of Upper Normandy, and are supposed to be descendants of those Saxons who settled on the French coast during the period of the Merovingian kings. Some interesting historical associations attach to the castle of Dieppe. Here Henry IV.—the people of D. having been the first to acknowledge his right to the throne of France—retired before the forces of the league, previous to the decisive battle of Arques, fought within 4 m. of D.; and here the duchess of Longueville, so noted as a leader of the party of the Fronde, sought refuge for a time from the royal power she had defied. The castle is now occupied as a barrack. The other principal buildings are the churches of St. Jacques and St. Remi, the theater, and a bathing establishment. The town has several squares, and is adorned by nearly 70 fountains, which derive their supply of water from an aqueduct about 3 m. long. D., being one of the principal watering-places of France, has a great accession of visitors during the summer months; and a large number of huts for the accommodation of bathers, bathing-machines being dispensed with, line the shores. The manufactures are lace, fine linen, and paper; and the carved articles of horn, bone, and ivory have long been famous. There are also ship-building yards, sugar-refineries, rope-walks, and distilleries; and the fisheries—both coast and Newfoundland—are important, almost the whole of the population of the suburb of Pollet being engaged in them. D. is a favorite landing-place of English tourists visiting France. Pop. '76, 19,471. The rise of Havre has greatly injured the trade of Dieppe.

**DIE-SINKING**, the art of engraving the die or stamp used for striking the impression on coins, etc., and for stamping thin plates of metal into various devices.

The importance of die-sinking has much increased of late on account of the great extension of the process of stamping thin metal. Many kinds of work formerly bent into shape by the hammer and punch, are now struck by a few blows between suitable dies. As examples of these, we may mention the ornamental work of gas-fittings, window-curtain cornices, common jewelry, ornamental trays, dishes, boxes, etc. For such purposes, a pair of dies is required, one in relief, the other in intaglio, and the metal is pressed between them. Not only are ornamental articles stamped in this manner, but useful articles, composed of many parts, are made entirely by cutters and dies, each part being cut and stamped by a pair of dies, and then the parts united by another pair, the junction being effected by overlaps, which the uniting dies press into their places. See BURTONS. The astonishing cheapness of many of the Birmingham products is mainly due to the use of dies for doing by a single blow the work that

formerly required long and tedious manipulation. For further information on this, see STAMPING.

The most ancient and familiar application of dies, is in the striking of coins and medals; the method of sinking the dies used for this purpose will serve to illustrate the general method of die-sinking. Suppose the coin to be of the size of a shilling: a cylindrical piece of steel, about 3 or 4 in. in length, and 2 in diameter, is prepared by slightly rounding one end of the cylinder, then turning and smoothing upon the middle of this a flat face equal to the size of the coin. This blank die, which is carefully softened, is then engraved with the device of the coin in intaglio. This is a very delicate and artistic process, and is effected by a great number of careful touches with small and very hard steel tools. The face of the die is now hardened by placing it face downwards in a crucible upon a layer of bone-dust, or a mixture of charcoal and oil. In this position it is raised to a cherry-red heat, then taken out, and plunged in water. When properly tempered, it is in a state to be used for stamping the coin; but dies of superior workmanship, from which many impressions are required, are not thus directly used, as the expense of engraving is very great, and the risk of breakage considerable. This first engraved die, called the matrix, is therefore reserved only for making other dies. An impression in relief is made from this matrix on a small block of steel, which is called the puncheon; this is retouched and hardened, and from it the dies directly used for striking the coins or medals are impressed.

When the engraving is not very costly, a small number of impressions required, or a soft metal is to be stamped, as in livery buttons, for example, the work is stamped directly from the engraved die or matrix. When the device is in high relief, and the metal is hard, many heavy blows are required. Some of the finest large bronze medals require 200 or 300 blows for each impression, and the medal has to be annealed by heating between every 2 or 3 blows. It is on this account that the difference between the price of pewter and bronze medals of the same subject is so great, the pewter being so much softer. Copper, though harder than pewter, is much softer than bronze, and hence the reader will easily understand why the device on the new bronze coinage, manufactured at the new mint of Birmingham, is in much lower relief than the old copper coinage, as it would not pay to use repeated blows and annealing in striking common coins. An impression in high relief or deep intaglio may be obtained by a single blow by the *cliché* method. For this, a fusible alloy is used, such as type-metal, or still better, an alloy of 2 parts bismuth, 1 lead, and 1 tin, which fuses at about  $212^{\circ}$ , and becomes pasty before solidifying. The metal is poured into a box or tray a little larger than the die, and when in a pasty condition, the die is placed over it, and struck smartly with a heavy mallet or a coining-press. A steel die is by no means necessary for this: sharp impressions may be obtained from bronze medals themselves, or even from wood and plaster casts. A cliché mold may be made in the first instance from the medal, and then a cliché relief from this mold, if the process is skillfully conducted. The skill required consists mainly in striking the blow with a force proportionate to the depth of the impression and the softness of the metal, and in selecting the right moment for doing so, just as the fused metal is on the point of solidifying; for, if too fluid, it will merely be driven aside; and if at all set, an imperfect impression results. The metal should be of about the consistence of melted sealing-wax, and then the surface is set by contact with the cool die or medal, while the body of the metal still yields to the pressure. Cliché molds are admirably adapted for electro-depositing.

**DIES IRÆ**, the name generally given (from the opening words) to the famous mediæval hymn on the last judgment. On account of the solemn grandeur of the ideas which it brings before the mind, as well as the deep and trembling emotions it is fitted to excite, it soon found its way into the liturgy of the church. The authorship of the hymn has been ascribed to Gregory the great, St. Bernard of Clairvaux, Umberto, and Frangipani, the last two of whom were noted as church-hymnists; but in all probability it proceeded from the pen of the Franciscan, Thomas of Celano, a native of the Abruzzi, in the kingdom of Naples, who died about the year 1255. When the church adopted it, and made it a portion of the service of the mass, cannot be ascertained with any exactness, but it must have been in any case before 1385. Several alterations were then made in the text; that, however, is believed to be the original which is engraved on a marble tablet in the church of St. Francis at Mantua. Germany has produced many translations of the hymn, such as those of Schlegel, Fichte, and Bunsen. It was translated into English by Richard Crashaw in the 17th c., and by Lord Macaulay, Lord Lindsay, the Rev. Isaac Williams of Oxford, and others in our own day. Sir Walter Scott has introduced two or three of the opening verses into his *Lay of the Last Minstrel*. The following are the most effective stanzas of the original Latin:

Dies iræ, dies illa  
Solvat sæculum in favilla,  
Teste David cum Sibylla.

Tuba mirum spargens sonum  
Per sepulchra regionum  
Coget omnes ante thronum.

Mors stupebit et natura,  
Quoniam resurget creatura  
Judicanti responsura.

Liber scriptus proferetur,  
In quo totum continetur  
Unde mundus judicetur.

Judex ergo cum sedebit,  
Quidquid latet apparebit,  
Nil inultum remanebit.

Quid sum miser tunc dicturus,  
Quem patronum rogaturus,  
Quum vix justus sit securus?

Rex tremendæ majestatis,  
Qui salvandos salvas gratis,  
Salva me, fons pietatis.

Recordare, Jesu pie,  
Quod sum causa tuæ viæ:  
Ne me perdas illa die.

Querens me sedisti lassus,  
Redemisti cruce passus,  
Tantus labor non sit cassus.

Qui Mariam absolvisti  
Et latronem exaudisti,  
Mihi quoque spem dedisti.

Inter oves locum præsta,  
Et ab hædis me sequestra,  
Statuens in parte dextra.

Amen.

**DŶESIS**, a term used by the ancient Greeks, in the division of musical intervals, of which they had three varieties. In modern music, the D. is understood to be the difference between the small and the great semitone, as from C to C sharp, and from C to D flat.

**DIESKAU**, **LUDWIG AUGUST VON**, 1701-67; a German soldier who served in the French army, adjutant to marshal Saxe, whom he accompanied in the campaigns in the Netherlands, becoming brig.-gen. in 1748. He was sent to Canada in 1755, to command the French troops. With a force of 200 regulars, 600 Canadians, and 600 Indians, he moved up lake Champlain to attack fort Edward. When within 2 m. of the fort he first apprised his troops of his intention, but the Canadians and Indians, fearing the English cannon, declined. But on Sept. 8, 1755, the attack was made. The French marched along the road directly upon the English center, halting 150 yards from the breastworks. The French regulars made the central attack, while the Indians and Canadians dispersed on the English flanks. As soon as the English artillery began to play the Canadians fled to the swamps, and Dieskau was compelled to order a retreat, which was in fact a rout. The baron, who had received a wound in the leg, was found leaning against a stump, entirely alone. While feeling for his watch, an English soldier, suspecting him to be reaching for a pistol, fired into his hip, and he was taken to the fort a prisoner. He was liberated in 1763, and returned to Paris, where he died.

**DIEST**, a t. of Belgium, in the province of Brabant, on the river Demer, 17 m. n.e. of Louvain. It is a walled town, and its fortifications have recently been so improved as to render it a place of great strength. D. has considerable manufactures of hosiery and woollen goods, but its chief products are beer—which is of excellent quality, and largely exported—and gin. Here a great horse-fair is held annually. D., which was once a feudal barony, under the dominion of the princes of Orange, was taken by Marlborough in 1705. Pop. '70, about 8,000.

**DIESTERWEG**, **FRIEDRICH ADOLF WILHELM**, 1790-1866; a German teacher educated at Tübingen. In 1832, he was made director of the seminary for teachers of the Berlin city schools, which charge he held till 1850. He wrote many text-books on mathematics, geography, etc., and manuals for teachers, all of which have wide popularity. He was an advocate of the theories of Rousseau, Pestalozzi, and modern liberalism in general.

**DIET**. Man and animals generally require that their food should be of such a nature as to compensate for the wear and tear of the tissues which is perpetually going on, and as at the same time to keep up the animal heat at its proper standard. Various classifications of the food of man have been at different times proposed, but those which have been most generally accepted are that of Dr. Prout—in which the different kinds of food are grouped in definite chemical classes—and that of Liebig, which has reference solely to the ultimate destination of the food in the animal economy.

Dr. Prout classifies all kinds of food under these heads: 1. The *aqueous*; 2. The *saccharine*; 3. The *oily or oleaginous*; and 4. The *albuminous*; to complete which, we ought to add 5. The *gelatinous*, and 6. The *saline*—whilst Liebig makes only two classes: 1. Those consisting of nitrogenized matters, which are adapted for the formation of blood, and which he terms the *plastic elements of nutrition*; and 2. The non-nitrogenized substances, which from their large amount of carbon, serve (as fuel) to keep up the animal heat, and which he names the *elements of respiration*. Recent investigations, however, throw doubt on Liebig's view, that before food can be made available for the performance of work, it must first be turned into muscular tissue and then oxidized. Now it

seems most probable that it is the oxidation of the non-nitrogenous substances, and not of muscle, that contributes chiefly to the production of muscular force. Starch, fat, and the other non-nitrogenous substances would therefore have to be regarded as force-producers, and not, as formerly, mere heat-givers. We shall therefore adopt Prout's classification. It was based on the consideration, that the milk (the only *single* article of natural food that serves to support the animal body) is made up of substances which may be taken as representatives of his groups; for this, our earliest natural diet, contains water, sugar (representing his saccharine group), butter (representing his oleaginous group), caseine (a nitrogenous matter very similar to albumen, and representing his albuminous group), and salts; and recent researches have shown that the yolk of the egg, which serves for the nourishment of the chick or other young animal before birth, similarly contains one or more representatives of the aqueous, saccharine, oleaginous, albuminous, and saline groups.

We shall now briefly consider these individual groups, and the uses to which the substances included in them are applied in the animal economy.

1. The *aqueous* group includes water and all the fluids which we use as drinks; and we must additionally bear in mind that all the varieties of animal and vegetable food which we term solids, in reality contain it, generally in great abundance; thus, for example, uncooked beef contains from 70 to 80 per cent, and some vegetables even a larger proportion of water. The uses of water are sufficiently obvious from the abundance in which it occurs in all the most important fluids of the body, as the blood, and the various digestive fluids. See DIGESTION, ORGANS AND PROCESS OF.

2. The *saccharine* group includes the different varieties of sugar, starch, gum, and cellulose, together with vinegar. This group is chemically characterized by all its members being included in the formula  $C_aH_bO_b$ ; that is to say, they consist of carbon, together with hydrogen and oxygen in the proportions in which these elements form water. Hence (excepting vinegar) these substances have received the name of carbohydrates.

Of the sugars, grape-sugar or *glycose* is the most important, partly from its frequent occurrence in ordinary articles of food, such as fruits of most kinds, honey, etc., and partly because it is the form of sugar into which starch (a most abundant ingredient in most kinds of vegetable food) is converted by the saliva, and pancreatic and intestinal juices, before it is fitted for absorption or any further changes. Since the sugars (which may thus be regarded as including starch) do not, in the normal condition, pass into the excretions, but are oxidized in the blood into carbonic acid and water, as ultimate products, they must contribute materially to the support of the animal heat. But they have other uses which we shall endeavor to explain, and which will, we trust, be intelligible if this article is read in conjunction with that on DIGESTION, to which we have already referred. Before becoming oxidized into their final products, they undergo various phases of less perfect oxidation, in which lactic, acetic, butyric, and other acids are evolved, of which the most important and abundant is lactic acid, which is found in considerable quantity in the small intestine, where it is doubtless of service in contributing to dissolve any nitrogenous matters which have escaped the action of the gastric-juice. Another use of these acids which are developed from the sugars is, that by acidifying the albuminous intestinal contents, they greatly increase their diffusibility through the intestinal membranes into the lacteals, and probably the capillaries. Here we probably have the clew to the therapeutic use of acids in various disorders of the chylopoietic viscera. Under certain conditions, the sugars are also converted into fat in the body.\*

The remaining carbo-hydrates are of little or no value as food. There has been much difference of opinion as to whether gum can be taken up and applied to any definite uses in the organism; but the great mass of the most trustworthy observations seem to show that it passes through the system unchanged. Independently of experiments on animals by Boussingault, Lehmann, and others, Dr. Hammond (an American chemist and physician) found from experiments upon himself (1) that gum is altogether incapable of assimilation, and therefore possesses no calorific or nutritive power whatever, but is, on the contrary, a source of irritation to the digestive organs; and (2) that in consequence of the above fact, the solids of the urine during a purely gum-and-water diet are entirely derived from the waste of the tissues of the body, while the carbon exhaled (as carbonic acid) from the lungs is derived from the consumption of the fat.

Cellulose, or the substance of the vegetable cell, resists the action of the digestive fluids, and reappears unchanged in the fæces.

Vinegar is probably only of use indirectly in softening animal textures which are taken as food.

3. The *oleaginous* group includes all the fats and oils, whether derived from the animal or the vegetable kingdom. The members of this extensive group are composed of carbon (ranging from 60 to 80 per cent) and hydrogen, with a little oxygen. Fat which has been taken with the food is mainly absorbed by the lacteals, although a portion of

\*The researches of Boussingault on milch-cows, of Milne Edwards and others on bees, and of Lacaze-Duthiers on the insects inhabiting galls, distinctly show that starch and sugar are capable of being converted into fat in the animal organism.

it passes directly into the capillaries of the villi, as has been shown by microscopic examination, which has revealed the presence of fat-granules amongst the blood-corpuscles. The modifications which are impressed upon the fats, in order to prepare them for absorption, are explained in the article DIGESTION. Their uses in the system are various. In their oxidation in the organism, whether the process be gradual or rapid, a large amount of heat is liberated; and that they are oxidized, and for the most part ultimately resolved into carbonic acid and water, is evident, because they neither appear in any quantity in the excretions nor accumulate beyond a certain point in the organism. Moreover, in artificial, and doubtless in natural digestion, the presence of a little fat accelerates the solution of nitrogenous matters taken as food. Lastly, the occurrence of fat in milk, in the egg, in all plastic exudations, and in all highly cellular organs, is a clear indication that this substance plays an important part in the process of cell-formation; hence we may probably explain the therapeutic use of such medicines as cod-liver oil.

4. The *albuminous* group contains all those substances which are chemically known as the *proteine-bodies* (see *PROTEINE*), viz., albumen, fibrine, caseine, and the allied vegetable compounds, all of which are composed of very nearly the same proportions of carbon, hydrogen, nitrogen, and oxygen; while additionally they contain a little sulphur or phosphorus, or both: they all contain on an average about 15 per cent of nitrogen, a substance which has not occurred in the preceding groups. All these *proteine-bodies*, such as occur in the fluids of the egg, in animal flesh, in the curdy matter of milk, etc., are dissolved by the gastric-juice and intestinal fluid, and converted into matters termed *peptones*, which, although similar in their ultimate composition to the substances from which they are derived, differ from them in their greater solubility and more their ready diffusibility through animal membranes. Like the fats, they are chiefly absorbed by the lacteals, but to some extent by the capillaries. A reference to the chemical composition of the milk and of the fluids of the egg, shows that all the nitrogenous tissues in the body of the young animal must have been primarily derived from albumen or caseine; and it is established beyond all doubt that these substances are throughout life the essential producers of blood, and consequently of the various nitrogenous structures which are built up from that fluid.

5. The *gelatinous* group (which formed a part of Prout's albuminous group) includes the different varieties of gluten, obtained by boiling, from many animal tissues; as, for example, bone-cartilage, tendons, skin, hoofs, etc. All soups and jellies which stiffen on cooling contain it, and such substances are popularly, but erroneously, regarded as highly nourishing. Unlike the preceding group, from which they only slightly differ in ultimate composition, they do not appear to form new blood, and their uses are still so questionable, that we will merely notice one function of them, which has been suggested by Liebig—viz., that these substances may go directly to the formation of such tissues as yield gluten on boiling, and which, if this food were not taken, would have to derive their nourishment from the members of the preceding group.

6. The *saline* group. With the exception of common salt (chloride of sodium), which we take instinctively in additional quantity with most kinds of food, the members of this group are unconsciously taken in the different articles of solid and fluid food on which we live. Want of space prevents us from noticing the different foods which yield the individual salts; but when we invariably find phosphate and carbonate of lime in the bones, in fixed and definite proportions; when we invariably find a nearly fixed proportion of chloride of sodium, alkaline phosphates, and other soluble salts, in the blood, flesh, milk, etc.; and when, further, we find that these substances are being constantly eliminated by the urine, it is obvious that they must be replaced by the food if we would keep the organism in its normal state. The evil consequences of a deficiency of any of these ingredients of food are well known; thus, when too little phosphate of lime (to which bone owes its firmness and hardness) is taken into the system, or when too much is again taken out (as occasionally, during pregnancy, when the fetal bones require it for their ossification), fractures do not readily unite.

It is only comparatively recently—during the last quarter of a century—that physiologists have satisfied themselves, that in order to supply the wants of the system, food must consist of a combination of these groups; and that animals which are fed exclusively on food belonging to one of the groups—as, for example, albumen or fibrin—perish under symptoms of inanition, as certainly as if they had been deprived of all nourishment. As in the infant's milk we find the albuminous, oleaginous, saccharine, and saline groups represented by the caseine, butter, sugar, and salts, so, for other periods of life, the food, whether derived from the animal or vegetable kingdom, must contain a due (although not necessarily the same) proportion of the different types. Again, in judging of the nutritive value of any kind of food, we must take into consideration its digestibility. Thus, the experiments made by Dr. Beaumont on Alexis St. Martin, a Canadian, in whom there was, in consequence of a gun-shot wound, a fistulous opening leading from the exterior to the interior of the stomach, and recent experiments made by Busch on a woman with a fistulous opening into the jejunum (see *ALIMENTARY CANAL*), show, for example, that hard-boiled eggs, meat that has been boiled for a long time, and hard cheese, which is poor in fat, are less easily and rapidly digested than soft-boiled or fresh eggs, meat steeped in

vinegar, or moist, fat cheese, and that starch is much more readily converted into sugar when boiled than in the raw form.

As the nitrogenous constituents of the food (articles containing albumen, fibrin, etc.) are chiefly employed in the formation of the blood and the reproduction of the tissues, it was at one time thought that the quantity of nitrogen which any kind of food contained might be taken as a measure of its nutritive value; but this test is not altogether to be relied on, since the nitrogen in part depends upon the gluten-yielding matters, which probably contribute little or nothing to the formation of textures.

Both daily experience and chemico-physiological observations show us that the best kinds of food contain both fat and carbo-hydrates, in addition to albuminous matters. Instinct teaches us to combine highly amylaceous foods with fats; as, for example, bread and butter, beans and fat bacon; and the increased digestibility of such mixtures proves, no less than the simultaneous occurrence of fat and sugar in the milk and in the egg-fluids, that both substances are necessary, as independent ingredients of food, although, perhaps, one may temporarily serve as a substitute for the other. Unfortunately, we have no trustworthy data for enabling us to determine the proportion in which the different nutrient groups should be combined, so as to form the food best suited to the general wants of the organism. The proportions occurring in human milk are the following: 10 parts of plastic or blood-forming matter (caseine), 10 parts of fat (butter), 20 parts of a carbo-hydrate (sugar), and 0.6 of a part of salts. For the wants of adult life, a lesser ratio of plastic matter (albumen, etc.) would probably suffice.

The absolute quantity of food required for the maintenance of the human body in health varies so much with the age, sex, and habits of the individual, and with the circumstances in which he may be placed, that it is impossible to fix a standard applicable to every case; but from the consumption of food by large bodies of healthy men, such as our soldiers and sailors, we can determine with tolerable accuracy the *average* daily quantity. We extract the following remarks from Todd & Bowman's *Physiological Anatomy and Physiology of Man*. "Each seaman in the British naval service is allowed from 31 to 35½ ounces of dry nutritious food daily, of which 26 ounces are vegetable, and the rest animal; the latter consisting of 9 ounces of salt meat, or 4½ of fresh. Sugar and cocoa are also given. The soldier is allowed a pound of bread, and three quarters of a pound of meat. In most of the London hospitals, full diet, which is given to convalescent patients who need a liberal diet, consists generally of half a pound of meat, with from 12 to 14 ounces of bread, half a pound of potatoes, a pint of milk, and sometimes beer or porter—a pint of the former, or half a pint of the latter. The former dietary is destined for men who must be in readiness for the most active athletic exercises, requiring not only great muscular strength, but also considerable power of enduring fatigue. The latter is intended to recruit the powers of those who have been suffering from disease. If, now, we compare with these a dietary which has been found sufficient for the support of health in a state of more or less confinement, with a moderate amount of daily labor, we may fairly infer that the proper allowance for persons not engaged in actual manual labor lies between these extremes. In the union workhouses of England, able-bodied men obtain about 25 ounces of solid food daily, of which the quantity of meat does not exceed 5 or 6 ounces. In prisons, it has been found necessary to give a certain amount of animal food to prisoners who are subject to hard labor. Each of such prisoners, if confined to a term exceeding three months, and kept at hard labor, has a daily allowance of about 86 ounces of food, of which meat constitutes only a very small portion—namely, about 16 ounces in the week. The prisoner has obviously the advantage of the poor man, whose only crime is poverty; but there is doubtless sufficient justification for this in the fact, that the labor of the prisoner, and the mental depression which long-continued restraint and confinement induce, render a greater amount of nutriment necessary than the indigent would require, who seek in the workhouse a shelter from absolute want." For further details on this subject, which is one of great practical importance, we may refer to a paper by Dr. Lyon Playfair, "On the Food of Man under Different Conditions of Age and Employment," published in 1854, in the 56th volume of the *Edinburgh New Philosophical Journal*, and to a memoir by Dr. E. Smith upon "Prison and other Dietaries." See also Dr. Pavy's *Treatise on Food and Dietetics* (2d ed. 1875).

It appears, then, that a daily amount of food, varying from 35 to 25 ounces, is sufficient to maintain health; and of this a fourth or fifth part ought to be animal food; but in special cases, much more or much less may be taken without apparent injury. The smallest quantity of food upon which life is known to have been supported with health and strength, is that on which Cornaro—whose history is recorded in most books on D. and dietetics—states that he subsisted, in order to reduce extreme corpulence, for a period of 58 years—viz., 12 ounces of food, chiefly vegetable, with 14 ounces of light wine. In contrast with Cornaro's case, we may refer to instances recorded by Parry and other arctic voyagers of the voracity of the natives of those cold regions. A young Esquimaux, who was allowed "unlimited diet," availed himself of the privilege to the extent of devouring, in 24 hours, 35 lbs. of various kinds of food, including tallow-candles; and the Cossacks of Siberia are reported to consume daily from 12 to 20 lbs. of animal food.

An article upon D. would be imperfect without a reference to the best mode of dressing meat, for cooking and digestibility are closely allied. Most persons find meat that has been broiled most easily digested. The fire should be brisk, so that the albumen on the surface of the meat may be coagulated rapidly, and thus retain the internal juices. A similar rule applies, for the same reason, to boiling and roasting. When meat is to be boiled, it should be plunged into water already boiling; while, if soup is to be made, the meat should be put into cold water, and the temperature slowly and gradually raised—the object, in the former case, being to retain, in the latter, to extract, the nutritious fluids. (See *BOILING and BROILING*.) Fried meat and rich stews are usually very indigestible. Salted meat is not only harder and more indigestible than fresh meat, but the process of salting extracts important salt, and much of the nutrient juice from the meat; the only exception being fat pork, which is rendered more digestible by salting. On this subject, see Liebig's *Researches on Food*, 1847.

We shall conclude with a notice of certain substances which, although they are hardly entitled to be termed foods, may fairly be considered, from the universality of their use, to exert a definite influence on the organism, and to supply certain existing, although, perhaps, undefined wants. We refer to alcohol, tobacco, tea, and coffee.

From three series of observations made upon himself, Dr. Hammond arrives at the conclusion, that "alcohol increases the weight of the body, by retarding the metamorphosis of the old, and promoting the formation of new tissues, and limiting the consumption of fat." The respiratory and urinary excretions, and the fæcès, were invariably diminished. These effects occurring when the amount of food was below the quantity required to maintain the weight of the body, were productive of no deleterious result to the system; but when the food was sufficient to balance the waste from the excretions, and still more, when an excess of aliment over the demands of the system was ingested, the health was disturbed, and disease almost induced. Hence the laboring-man, who can hardly find bread and meat enough to preserve the balance between the formation and decay of his tissues, finds in alcohol an agent which, if taken in moderation, enables him, without disturbing his health, to dispense with a certain quantity of food, and yet keeps up the weight and strength of his body. On the other hand, he who uses alcohol when his food is more than sufficient to supply the waste of tissue, and, at the same time, does not increase the amount of his physical exercise, or drink an additional quantity of water (by which the decay of tissue would be accelerated), retards the metamorphosis, while an increased amount of nutriment is being assimilated, and thus adds to the plethoric condition of the system which excessive food has a tendency to produce.

Tobacco, according to the experiments of the same excellent observer, resembles alcohol in these respects, that when the food is sufficient to preserve the weight of the body, it increases that weight; and when the food is not sufficient, and the body, in consequence, loses weight, it restrains that loss; but it differs from alcohol in being unattended with any unpleasant effects upon the circulation, though its action on the brain is apparent in increased nervous excitement, followed by a pleasant feeling of ease and contentment. In these experiments, Dr. Hammond, who was not in the habit of using tobacco in any form, smoked 450 grains daily.\*

Tea and coffee are usually believed to have a somewhat similar effect to that which, as we have shown, is produced by alcohol and tobacco. The power of tea in arresting the waste of tissues has, however, been called in question. The value of alcohol and other stimulants was the subject of an elaborate controversy in several numbers of the *Contemporary Review* for 1878.

DIET, the assembly of the German states, a body of very ancient origin, in which the monarch formerly deliberated with his subjects upon measures proposed for the interests of the empire. It was a feudal, not a representative, body. When feudalism was destroyed it became a congress of princes, the emperor no longer presiding in person but by commissioners, and the princes sending envoys. The emperor was, theoretically at least, elected by universal suffrage, the chief men naming the candidate and the people ratifying their choice. The forms and rules of election were settled by the Golden Bull of 1356. The diet was constituted of the electoral college, the princes of the empire spiritual and temporal, and the free imperial cities. The electoral college was composed of three archbishops, representing the German church, and four secular electors. The princes, save in the matter of electing an emperor, had the same rights as the electoral college. The powers of the free imperial cities were quite limited. Each of the three colleges voted separately. When they agreed on a measure it was submitted to the emperor for ratification or for rejection, but he had no power to modify it. No measure affecting the welfare of the empire could be passed without the assent of the diet. The regular meetings were held twice a year. After the close of the thirty years' war the power of the body declined, until, in the words of Frederick the great, it became

\* Dr. Brinton, in his excellent article on "The Stomach and Intestine," in the *Cyclopædia of Anatomy and Physiology*, refers to an instance of the partial starvation of a large ship's crew on a long voyage, in which the *chewers* of tobacco were alleged to have endured hunger far better than the other sufferers, while the *smokers* did not enjoy the same advantage. This fact, however, does not invalidate our statement, and only shows, as we might *a priori* have expected, that the effects of chewing are more powerful than those of smoking. When the system receives its due supply of food, tobacco, if used at all, should be used in moderation.

“a mere shadow, a congress of publicists more busied with forms than things, like dogs who bay the moon.”

**DIET, DESERTION OF.** The proceedings under a criminal libel are in Scotland spoken of technically as a D., and when the libel is abandoned by the public prosecutor, or where he fails to appear, he is said to desert the diet. The effect of a judgment of the court declaring that the D. has been deserted, is to free the accused from prosecution under the particular libel or writ, but not to prevent a new process being raised on the same grounds. Where a defect or informality has been discovered in the libel, the prosecutor may apply to the court to desert the D. *pro loco et tempore*, by which means he reserves his right to insist of new, which would be lost were he to allow the trial to proceed to an acquittal. If the prosecutor's motion be, that the court shall desert the D. *simpliciter*, the accused will be thereby finally discharged; and this motion it is in his power to make, even after a verdict of guilty has been returned by a jury. In point of law, the lord advocate, or his depute who is prosecuting in his name, has it in his power at the very last to save the life of a prisoner, either by moving the court to desert the D., or by declining to move for sentence. The power, however, is one which public opinion in the present day effectually restrains him from exercising, and which, if once exercised, would certainly be abolished.

**DIETARY, MILITARY.** The chief matters concerning the D. or sustenance of the troops in the British army, and, indirectly, in those of other countries, will be found noticed under **BAKERIES, ARMY; COMMISSARIAT; COOKERY, ARMY; and RATION.**

**DIETARY, NAVAL.** In fitting out ships for the royal navy, the quantity of victuals is calculated on two data—the established allowance or ration of certain articles, and the average experience of past years in regard to certain others. Under the first category, the ration is everywhere equal, from the admiral down to the humblest sailor; under the second, the differences are very wide. Certain articles are regarded as “non-guaranteed” to the ordinary crew, to be given or withheld according to circumstances: such as fresh meat, preserved meat, lemon-juice, and wine.

The D. in relation to kind and quantity of food has been changed from time to time. In 1844, the daily ration was set down thus: 1 lb. biscuit,  $\frac{3}{4}$  lb. salt meat,  $\frac{1}{2}$  lb. vegetables,  $1\frac{1}{2}$  oz. sugar, 1 oz. chocolate,  $\frac{1}{4}$  oz. tea, and  $\frac{1}{2}$  pint rum. When the meat was beef,  $\frac{3}{4}$  lb. flour was added; when pork,  $\frac{1}{2}$  pint of pease in lieu of the flour. Besides these daily allowances,  $\frac{1}{2}$  pint oatmeal was given weekly, and vinegar when wanted, usually also half a pint per week. Fresh vegetables being not at times obtainable, preserved vegetables may not be in store, and circumstances may render it easy to obtain supplies of fresh meat, suet, raisins, currants, loaf-bread, rice, sago, coffee, cocoa, barley-m meal, butter, cheese, onions, leeks, wine, beer, etc. At such times the dietary undergoes a temporary change, very acceptable to the crew. If the sailors draw less than their rations, they receive a money equivalent at stated intervals. The cost of the dietary to the state, on the basis of 1844, was about £18 per man per annum.

The British government have never attempted the temperance system in the navy, but they offer facilities to such seamen as choose to adopt it. In 1847, a plan was introduced for giving tea and sugar in lieu of rum. Many of the seamen have in this way abandoned spirituous liquors, but not to so great an extent as the seamen of the U. S. navy.

In 1859, the D. was made more liberal in several particulars. The scale of provisions now stands thus: Daily—biscuit or soft bread,  $1\frac{1}{2}$  lbs.; spirit,  $\frac{1}{2}$  pint; sugar, 2 ozs.; chocolate, 1 oz.; tea,  $\frac{1}{4}$  oz. Weekly—oatmeal,  $\frac{1}{2}$  pint; mustard,  $\frac{1}{2}$  oz.; pepper,  $\frac{1}{4}$  oz.; vinegar,  $\frac{1}{2}$  pint. Daily when procurable—fresh meat, 1 lb.; vegetables,  $\frac{1}{2}$  lb. Daily when these are not procurable—salt pork or salt beef, 1 lb.; split pease,  $\frac{1}{2}$  pint; or 9 ozs. flour,  $\frac{3}{4}$  oz. suet,  $1\frac{1}{2}$  ozs. currants or raisins.

The D. for emigrants is regulated by law. Every emigrant-ship is bound to be provided with certain kinds and quantities of provisions, according to the number of emigrants and the length of the voyage. The chief owners of passenger-ships engaged in the Australian and other distinct trades, now pay great attention to this subject, as one which affects the good name of the several firms.

**DIETERICH, JOACHIM FREDERICK CHRISTIAN**, an eminent veterinary surgeon, was b. on the 1st of Mar., 1792, at Stendal, in Prussia. In 1818, he undertook, at the instance and expense of the Prussian government, a tour through France, Würtemberg, Bavaria, Austria, and Hungary. On his return, he was appointed to a chair in the veterinary college in Berlin, which he held for four years. In 1830, he accepted a post in the general military school of Berlin, where, in 1841, he was appointed professor in ordinary. His publications, which are widely known, and have been translated from the German into various languages, include *Pulmonary Consumption in Cattle* (Berlin, 1821); *Manual of Veterinary Surgery* (1822); *Manual of Special Pathology and Therapeutics for the Use of Veterinary Surgeons* (1828); *Manual of the Practical Knowledge of Horses* (1834); *Manual of Obstetrics* (1845); *Manual of the Education of Domestic Animals* (1848); *The Principal Defects of Horses, and the Mode of Diagnosing Them* (1853).

**DIETERICI, KARL FRIEDRICH WILHELM**, 1790–1859; a native of Berlin, educated at Königsberg, devoting his attention chiefly to mathematics. He was an engineer in

Blücher's army, 1813-15, and in 1820 was engaged in the ministry of public instruction. In 1834, he became professor of political science in the university of Berlin, and in 1844, was placed at the head of the statistical bureau. He published a number of important works on political economy and statistics.

**DIETRICH** of BERN, the name under which the Ostrogoth king, Theodoric (q.v.) the great, appears in the German heroic legends; in which by Bern, his capital, Verona is to be understood. As early as the 7th c., he would seem to have become the center of a distinct cycle of legends. A little later, he was, with a not unusual disregard of all historical truth, brought into connection with the traditions of Attila, or Etzel. According to these legends, D. is said to have fled from Italy before Ottacher (Odoacer), or Ermanarich; to have met, along with his attendant vassals, with a hospitable reception from Etzel; but after many years, to have again got possession of his kingdom. The extermination of the royal house of Burgundy by Attila, which is an historical event, was the cause that D., as well as Etzel himself, was woven into the Burgundian and Frankish Siegfriedssage; and thus he appears, in the second part of the *Nibelungen*, at Etzel's court, and is handled by the poet with special predilection. There have been numerous poems, besides, of which D. was the center and principal hero. It is very probable that the *Hildebrandslied*, of the 8th c., is a fragment of such a poem. Except this, we have only late versions of these legends; for example, *Schlacht vor Ruben* (Ravenna) of the 13th c.; *Alphart's Tod* (13th c.); *Züerg Laurin, oder der kleine Rosengarten* (15th c.); *Diétrich's Ahnen*; *Diétrich's Flucht*, etc.

**DIETS** of **COMPEAR'ANCE**, in the law of Scotland, are the days on which a party to a civil or criminal process is cited to appear in court. Formerly, there were two diets, because there were two summonses; but by the judicature act, in 1825, it was enacted that all summonses should henceforth proceed on one diet. By 13 and 14 Vict. c. 36, s. 21, the period allowed to the defender (see **INDUCE**) was shortened from 20 to 14 days for persons within Scotland; and for persons in Orkney, or in Shetland, or furth of Scotland, from 40 and 60 days respectively, to 21 days in both cases. In the sheriff-courts, the period is 6 days (16 and 17 Vict. c. 80). See **SUMMONS**, **INDICTMENT**, **INDUCE**.

**DIEU ET MON DROIT** (God and my right). The parole of Richard I., at the battle of Gisors, 1198, signifying that he was not subject to France, but owed his power to God alone. They were victorious over the French, and the battle word was adopted as the motto on the coat of arms of England. During the reign of queen Anne, *Semper eadem* ("Always the same") was substituted, but the former motto was restored by her successor.

**DIEZ**, **FRIEDRICH CHRISTIAN**, the founder of the philology of the Romanic languages, was b. at Giessen, 15th Mar., 1794, and educated at Giessen and Göttingen. During the greater part of the years 1819-20, he lived, at Utrecht as a domestic tutor. In 1822, he went to Bonn as a *privat-docent*, and in 1830 was there appointed professor of modern literature. His first work, *Allspan. Romanzen*, was issued in 1821. Since then, he has published a great number of valuable works on the Romanic languages, two of which are worthy of special mention—the *Grammatik der Romanischen Sprachen* (Grammar of the Romanic Languages, 3 vols., Bonn, 1836 to 1842), and the *Etymologisches Wörterbuch der Romanischen Sprachen* (Etymological Dictionary of the Romanic Languages, Bonn, 1853). The last of these works, in particular, is recognized not only by Germans, but by the scholars of all the Romanic nations, to be the basis for the scientific study of all the Romanic languages. He was actively engaged in work till his death, May 29, 1876.

**DIFFERENTIATION**, in mathematics, the process of finding the differential of a function. When a function of two or more independent variables is differentiated as if all the variables but one were constants, the operation is called partial differentiation.

**DIFFERENCE**; **DIFFERENCES**; **CALCULUS OF FINITE DIFFERENCES**. The word difference means usually the excess of one quantity over another of the same kind, and this is its meaning in arithmetic. In the higher branches of mathematics, however, it has a peculiar meaning, which we shall briefly explain. When we have a series of numbers connected by a regular, though not obvious law, the character of that law may be detected by forming a new series of the *differences* between each term of the original series and the next, and then treating the new series (which we may call the series of "first differences") in the same way; and so on, till we reach a series of differences the law of which is manifest. Thus,

Given series, . . .	4,	7,	11,	18,	31,	54,	92,	151
First differences, .	3,	4,	7,	13,	23,	38,	59	
Second differences, .	1,	3,	6,	10,	15,	21		
Third differences, . .	2,	3,	4,	5,	6			

The law of the series of third differences is manifest; we see that its next term must be 7, which gives 28 as the next term of the series of second differences, 87 as the next of

the first differences, and so 238 for that of the original series, which we can thus continue to any number of terms. To take a simpler case. Let the series be

	43,	47,	53,	61,	71
First differences,	4,	6,	8,	10	
Second differences,	2,	2,	2		

Here the law is manifest in the first differences, and we should be able to calculate the series if we knew the first terms of the three series; viz., 43, 4, 2. It is on this principle that calculating machines (q.v.) can be constructed to compute tables of logarithms, etc. Out of the method of differences sprung the calculus of finite differences, first treated by Dr. Brook Taylor, under the name of the method of increments. This calculus has nothing to do with the transcendental analysis. See CALCULUS DIFFERENTIAL, etc. It deals with the changes of functions when *definite* increments are made to the variables; while the transcendental analysis considers only their changes when indefinitely small or infinitesimal additions are made to the variables. It would be out of place here to attempt an account of the calculus of finite differences. See FUNCTIONS.

**DIFFERENCES**, in heraldry, though often, or indeed generally, confounded with marks of cadency (q.v.), have, in strict usage, a totally different function—the former being employed to distinguish brothers and their descendants after the death of the father, the latter whilst he is still alive. Differences in this limited sense may consist either of a chief added to or a bordure placed round the plain shield borne by the head of the house; or should the shield exhibit any of the ordinaries (q.v.), as the bend, fess, pale, etc., the difference may be indicated by an alteration on the lines. The proximity of the bearer to the head of the house is indicated by the character of the line by which the differencing chief, or bordure, or ordinary is marked off from the field, the following being the order usually observed: the first or eldest brother, on the death of his father, inherits the pure arms of the house; the second brother, if the difference is to consist of a bordure, carries it plain; the third, ingrailed; the fourth, invected; the fifth, embattled; etc. Other modes of differencing have been invented by heralds, and are not unknown to practice; such, for example, as changing the tinctures either of the field or of the principal figures, of which Nisbet gives many famous examples—altering the position or number of the figures on the shield, adding different figures from the mother's coat or from lands, and the like. Where the cadet is far removed from the principal family, if the field be of one tincture, it is sometimes divided into two, the charge or charges being counter-charged, so that metal may not lie on metal, or color on color. The confusion between differences and marks of cadency, above referred to, is by no means peculiar to the heraldic usage of England, though there it is more prevalent than in Scotland. In France, the cadets of the house of Bourbon have been in the habit of continuing these marks, and at the present day, as in Mackenzie's time, the label or lambel is to be seen on the arms of all the members of the Orleans family. That no distinction between what we call marks of cadency and differences was there observed, is further apparent from the fact that, whilst such was the practice of the house of Orleans, the house of Anjou carried a bordure gules, and that of Alençon a bordure gules charged with eight bezants. In Germany, sir George Mackenzie says that the several branches of great families distinguish themselves only by different crests (*Precedency*—Works, ii. 616); and he gives as the reason, that all the sons succeed equally to the honors of the family. In Britain, and in France, some change is always made on the shield as carried by the head of the house; but the practice even of good heralds has been so irregular, as to bring the rule very nearly to what Mackenzie holds to be the correct one—viz., that every private person should be allowed, with the sanction of the proper authorities, "to make what marks of distinction can suit best with the coat which his chief bears."

**DIFFERENCES, CALCULUS OF.** See DIFFERENCE.

**DIFFERENTIAL CALCULUS.** See CALCULUS.

**DIFFERENTIAL THERMOMETER.** See THERMOMETER.

**DIFFRACTION, or INFLECTION**, of the rays of light. It was observed by Grimaldi that if a beam of the sun's light be let into a dark room through a very small hole, the shadows of things in this light will be larger than they ought to be if the rays passed by the bodies in straight lines, and that these shadows have three parallel fringes, bands, or ranks of colored light adjacent to them.

This phenomenon was originally known under the name of diffraction, and was supposed to arise from the refraction of the atmosphere. This explanation was disproved by the observations of Newton, who, from the conception which he was led to form of it, called the phenomenon the "inflection of the rays of light." It is now identified with a larger class of phenomena, which have been much more completely explained in the later development of the theory of light, and are assigned, on the hypotheses of Fresnel, to the interference of undulations. See INTERFERENCE. The observations and experiments of Newton on the subject, as detailed in the third book of his work on Optics, are, however, extremely interesting and instructive, and with regard to accurate observation and description, apart from the imperfect state of the theory, leave nothing to be desired.

Having made in a piece of lead a small hole with a pin, whose breadth was the 42d part of an inch, Newton let into the darkened chamber a beam of the sun's light. In this light, the shadows of all bodies were bordered with three parallel fringes or bands of colored light. The shadow of a hair, too, was found to be much broader than the hair itself, and fringes of light were observed within it.

Again admitting light into the darkened apartment by a hole a quarter of an inch wide, he allowed it to pass between two knife-edges parallel to one another. In this case, owing to the breadth of the hole by which the light was admitted, the fringes did not appear within the shadows of the knives until the knife-edges were brought to approach one another, when they appeared. By making the hole smaller through which the light was admitted, they became more distinct. "As the knife-edges continually approached one another, the fringes grew distincter and larger, until they vanished. The outmost fringe vanished first, and the middlemost next, and the innermost last; and after they were all vanished, and the line of light which was in the middle between them was grown very broad, a shadow began to appear in the middle of this line, and divide it along the middle into two lines of light, and increased until the whole light vanished. This enlargement of the fringes was so great, that the rays which go to the innermost fringe seemed to be bent above twenty times more when this fringe was ready to vanish than when one of the knives was taken away."

The order of these phenomena is then made clear by the following experiment: "I caused the edges of two knives to be ground truly straight, and pricking their points into a board, so that their edges might look towards one another, and meeting near their points, contain a rectilineal angle, I fastened their handles together with pitch, to make this angle invariable. The distance of the edges of the knives from one another at the distance of four inches from the angular point, where the edges of the knives met, was the eighth of an inch; and therefore the angle contained by the edges was about  $1^{\circ} 54'$ . The knives thus fixed together I placed in a beam of the sun's light, let into my darkened chamber through a hole the 42d part of an inch wide, at the distance of 10 or 15 ft. from the hole." When the fringes of the shadows of the knives fell perpendicularly upon a paper at a great distance from the knives, they were in the form of hyperbolas.

The best mode for exhibiting the phenomena of diffraction, and that now generally adopted for that purpose, is as follows: The rays of sunlight being reflected horizontally through an aperture into a darkened apartment, are concentrated by a combination of lenses to a very small focus. By this means the light is made to diverge from a very small circle, with the advantage of a greater concentration of light than is obtained by simply admitting the sunlight through a small aperture. The edges of the shadows of every object placed within the cone of light diverging from this focus, will exhibit the fringes above described.

By means of metal-leaf arranged upon a plate of glass, shadows can now be thrown upon a screen, so as to exhibit at once all the most peculiar phenomena of this class.

On the assumption of Fresnel, the explanation of the whole phenomena above described is most complete and satisfactory, the fringes and dark lines being produced by the undulations alternately strengthening or destroying each other. A very beautiful experiment, devised by Fresnel for the purpose, is found to furnish a complete verification of the theory. See INTERFERENCE.

**DIFFUSION**, the gradual dispersion of particles of one liquid or gas among those of another—or of the particles of a solid in a liquid holding it in solution. It is of the greatest importance in terrestrial physics, being the cause of the uniform composition of the atmosphere at all elevations, and one of the causes of the speedy dissipation of noxious gases and vapors in the open air, and of the nearly uniform saltness of the sea, etc., so necessary to animal and vegetable life.

We shall consider the above cases in detail, and in addition the transfusion, as it has been called, which occurs when different gases or liquids are separated from each other by a porous plate or membrane. The principal experiments on this subject are those of Graham and Bunsen—to be found in the *Philosophical Transactions* or Graham's *Chemistry*, and in Bunsen's *Gasometry*.

1. *Diffusion of Gases*.—If two flasks be filled, one with hydrogen, the other with chlorine, and connected by a long tube fitted into their necks by corks—in whatever position the compound apparatus be placed it will be found that the gases mutually interpenetrate—in this particular case the color of the chlorine enables us to follow by the eye the course of the diffusion. When the mixture has attained its permanent state, each of the gases is found to be uniformly diffused through the whole containing space, precisely as it would have been had the other not been present. In fact, the presence of a second gas seems merely to affect the time which the first takes to distribute itself equably throughout the vessel, and in no other way to influence the final result. (Dalton, long ago, suggested the analogy of the passage of water among stones in the bed of a river.) The pressure of the mixture is the sum of the pressures corresponding to each of the gases, if separately occupying the space which they jointly fill; and the same is true of a mixture in any proportions of any number of gases, so long, at all events, as they do not act chemically upon each other.

Precisely the same is true of vapors. If, for instance, a few drops of ether be injected into an exhausted receiver, there will be an almost instantaneous conversion of a definite quantity into vapor, so that its tension shall have a certain value depending on the temperature alone. If air be present in any quantity whatever, the vaporization will proceed more slowly, but the final amount converted into vapor will be the same as in the former case. A familiar illustration of this is afforded by the dew-point, which is a temperature merely, having no connection with the height of the barometer.

Next let us take the case of a gas forced by difference of pressure, from one vessel to another through a very small hole in a thin metallic plate—one of the vessels, for instance, being full of the gas, and the other connected with an air-pump kept continually in action. Experiment and theory, such as it is, agree in giving in this case, for the velocity with which the different gases pass through the orifice, under similar circumstances as to pressure, a result inversely proportional to the square root of the density of each gas. Now, if, instead of the plate with the small hole, we substitute a thin layer of bladder or other membrane, or a thin disk of plaster of Paris, it appears from experiment that the results are sensibly the same. Thus, if we have the same gas at different pressures on opposite sides of such a layer or disk, the rate of passage of the gas through it, from greater to less pressure, will, for the same pressures, but different gases, vary according to the above law; and, moreover, the presence of a second gas will in no degree modify the rate of transfusion of the first. If, therefore, a glass tube, say an inch in diameter, and 2 or 3 ft. long, have a diaphragm of plaster of Paris formed near one end, and that end ground flat, so as to be perfectly closed by a glass plate, it may be filled with hydrogen by displacement, its other and lower extremity being plunged into water, and care being taken not to wet the diaphragm. If the glass plate be now removed, transfusion will take place—hydrogen passing out as if into a vacuum, and the constituent gases of air entering also as if into a vacuum. On account of the comparative lightness of hydrogen, the velocity with which it escapes will be considerably greater than that with which the others enter; so that the immediate effect will be a rise of the water in the tube. After a short time, the whole of the hydrogen escapes, and the tube will contain only air. The proportion of the volume of the latter to that of the hydrogen may be calculated from the above law—remembering that the hydrogen is practically diffusing into a vacuum all along, and the air entering by the pressure of the atmosphere in excess over that of the air in the tube. Allowing for the unavoidable errors of experiment, the verifications of these results are very satisfactory. It has been attempted to deduce these laws as consequences of the dynamical theory of gases. See a remarkable paper by Maxwell in the *Philosophical Magazine* for 1860.

Bunsen has suggested the application of the method of diffusion to the very important question in gas analysis—whether the constituents of a gas, as determined by the usual methods, are merely *mixed*, or are chemically united. It is evident that, in general, the diffusion rate of a mixture of two gases will differ from that of a compound of the same.

2. *Diffusion of Saline Matters in Solution.*—If a strong brine be placed in the bottom of a tall glass jar, pure water may be carefully introduced above it, so that no immediate mixture takes place. If the whole be allowed to stand, the salt is gradually diffused through the vessel, which, after a sufficient time, will be found to contain a brine of uniform strength. Experiments have been carefully made to determine, in such a case as the above, the distribution of the salt through the vessel at various periods *before* the permanent state has been arrived at. They have been compared with the results of the theory now to be explained, and the coincidence has been found very satisfactory. The theory assumes that the rate of diffusion between contiguous layers of the water in the cylinder is proportional to the excess of salt in one layer above that in the next—the co-efficient of proportionality involving a special constant of diffusion for the particular salt experimented upon. This is precisely the assumption that is made about the linear conduction of heat in a homogenous solid, or the propagation of electricity in a wire.

The partial differential equation to which all of these cases are reducible,  $\left(C \frac{du}{dt} = \frac{d^2u}{dx^2}\right)$ ,

was obtained, and its complete solution exhibited in various forms long ago by Fourier, in his *Théorie de la Chaleur*, one of the most remarkable mathematical investigations of last generation. See HEAT, CONDUCTION OF, and ELECTRICITY, THEORY OF. It is curious to consider the heating of a metallic rod, or the solution of a few crystals of salt in a tall glass jar full of water, as problems thus directly allied to the signaling through the Atlantic cable.

Graham's method of determining the diffusion co-efficient of a salt in water was simple, and yet admitted of great precision in the determinations. A number of glass bottles, cast in the same mold, had their mouths ground flat, so as to be accurately closed by a plate of glass, which—when the bottle, filled with a solution of known strength, had been carefully placed in one of a series of equal glass jars, and covered with a constant amount of water—could be slipped off without producing any considerable disturbance in the fluid. After a measured time, the glass plate was replaced, and the amount of salt which had left the bottle accurately determined.

The following are the most important of the laws thus obtained; they are quite consistent with the theory above mentioned. For solutions of the same substance, of dif-

ferent degrees of strength, the rate of diffusion is proportional to the strength of the solution. Different salts seem to arrange themselves in groups as regards their diffusion co-efficients, the latter having simple numerical relations to each other. Analogy of chemical composition and of crystalline form appear to be the principal elements in the arrangement of the groups. The quantity diffused increases with the temperature, and at the same rate for all salts. The presence of a second salt in the solution, or in the water into which the diffusion takes place, if not in large quantity, appears not to affect the result, supposing, of course, that no chemical action takes place. It is evident that by this process a partial separation may be effected of salts which have different rates of diffusion, and do not act chemically on each other; and it is found that in certain cases even chemical compounds, such as alum, may be partially decomposed by the same means.

3. *Diffusion of Liquids. Osmose.*—If sulphuric acid be carefully poured through a tube into the bottom of a vessel filled with water, colored by an infusion of litmus, or red cabbage, the change of color of the vegetable dye will enable us to trace the gradual diffusion of the acid in the water. Here, the process, though probably on the whole quite analogous to the case of gases, occupies more time; but the final result is, as in the former case, an almost uniform mixture of the two fluids. There is no necessity for any special remark on this part of the subject, particularly as we have already adverted to the theory of this process. But if different fluids be separated by a membrane or diaphragm, some extremely remarkable results are obtained, which were first carefully examined by Dutrochet. These have been attributed to the action of osmotic force, something of the same kind as capillary force, and probably a closely connected, if not identical form of molecular action. The theory of these actions is not yet well understood, but we shall endeavor to give from analogy a few attempts at explanation.

If an inverted funnel, with a very long stem, have a bladder tied over its mouth, and, being filled to the neck with sirup of sugar, be suspended so that the bladder is entirely under the surface of water in a dish, the sirup will pass through the bladder into the water, and the water will pass through in the opposite direction, but in far greater quantity—producing the extraordinary effect of a rise in the level of the fluid in the tube, which can with precaution be made to amount to a yard or two in the course of a few days. The points of the attempted explanation of this phenomenon are somewhat as follows: The bladder has more capacity for, or will absorb more of, water than of sirup. The first effect, then, is to saturate the bladder with water, very slightly mixed with sirup. On the lower side of the bladder, water, with a small quantity of sugar in solution, is diffusing into pure, or nearly pure water, this process will be a slow one; at the upper side, water (nearly pure) is diffusing into a strong sirup. Here, then, the effect is much greater, and thus a greater quantity of water passes upwards than of sirup downwards. Similar effects may be produced with a vast number of other liquids. Combined with capillarity, it is believed that these experiments explain the motion of the sap in vegetables, and various other phenomena in the vegetable and animal kingdoms.

**DIGAMMA**, an obsolete letter of the Greek alphabet, equivalent in sound to the English *v*. In some of the earlier Greek dialects the old  $\gamma$  was a kind of aspirate, which, from its form, like one capital *T* over another, was called digamma, and written  $\phi$ . The Pelasgians carried this aspirate into Italy, where it remained in Latin as a real consonant, in such words as *vinum*, *ovum*, from the Greek *φοῖνος*, *ῥῶον*. The digamma had disappeared as a character from the Greek language before the days of Homer.

**DIGBY**, a co. in s.w. Nova Scotia, on the bay of Fundy; 1300 sq.m.; pop. '71, 17,037. It has a rough surface, with numerous mountains, valleys, and lakes, and some small rivers. Digby is the chief town.

**DIGBY**, a small seaport of Nova Scotia on the bay of Fundy, reputed for its curing of a variety of small herrings or pilchards, which are smoked and dried for export; they have a high flavor, and are known in trade as Digbies. Pop. '71, 1570.

**DIGBY**, Sir KENELME, the son of sir Everard Digby, noted as one of the gunpowder plot conspirators, was b. in 1603, three years before the execution of his father. He was brought up in the Protestant faith, and at the age of 15 was entered at Gloucester hall, Oxford. After leaving the university, where he had acquired the reputation of great ability, he spent two years in continental travel. He returned to England in 1623, and was knighted in lord Montague's house. Under Charles I., he was a gentleman of the bedchamber, and held several public offices. In 1628, he equipped a squadron at his own expense, and sailed first against the Algerines, and subsequently against the Venetians. In 1632, on the death of Dr. Allen, of Gloucester hall, D. inherited his collection of books and manuscripts. In 1636, when in France, he was converted to the Roman Catholic faith. He returned to England in 1638, and on the breaking out of the civil war, he was imprisoned as a royalist in Winchester house, but in 1643 he was allowed to retire to France. At Paris, he was received with favor by the court, and made the acquaintance of Descartes. After Charles I. had fallen, D. returned to England, but the parliament forbade him the kingdom, under penalty of death. Retiring to the continent, he traveled in France and Italy, but in 1655, he was again in England, and was in frequent attendance at the court of the protector. He went again

to France, and busied himself with the preparation of philosophical papers. He returned to England in 1661, and died there in 1665. D. married a daughter of sir Edward Stanley of Tongue castle, in Shropshire, by whom he had one son.

His works are numerous, and on a great variety of subjects, comprising *A Conference with a Lady about the Choice of a Religion* (Par. 1638); *Observations on Spenser's Fairy Queen* (Lond. 1644); *A Treatise on the Soul, proving its Immortality* (Par. 1644); *Of the Cure of Wounds by the Powder of Sympathy* (Lond. 1658); and *Discourse on Vegetation* (Lond. 1661), etc. *The Private Memoirs of Sir K. Digby, etc., written by Himself*, were published in London in 1827. D.'s library, which was removed to France when the civil war broke out in England, became, on his death, the property of the French king.

DIGBY, KENELM HENRY, son of the Rev. William Digby, dean of Clonfert, b. 1800; educated at Cambridge, and graduated in 1823. He soon afterwards became a convert to the Roman Catholic church and began to write semi-religious works, among which are *Mores Catholici, or Ages of Faith; Compitum, or the Meeting of Ways at the Catholic Church; The Broad Stone of Honor, or Rules for the Gentlemen of England; Evenings on the Thames*; etc.

DI GEST, a name often given to the pandects (q.v.) of the civil or Roman law, because they contained "Legalia præcepta excellentiora digesta."

DIGESTER, PAPIN'S, is a strong boiler with a closely-fitting cover, in which articles of food may be boiled at a higher temperature than 212° F. As its name implies, it was invented by Papin, and a common form is the *autoclave*, where the lid can be turned round under clamps or ears, and thus be rendered steam-tight. The lid is fastened down by a screw, and the steam generated in the boiler is allowed to escape at a stop-cock, or by raising a weighted valve. The increased pressure to which the contents of the boiler are exposed, causes the boiling-point of the water to rise to 400° F., and occasionally higher. The digester is of great value as a means of preparing soups of various kinds, and especially in the extraction of gelatine from bones.

DIGESTION, ORGANS AND PROCESS OF. The function or process of digestion is one of the chief of those organic functions which are directly concerned in maintaining the life of the individual, inasmuch as it is that through which the animal is enabled to receive aliment, and to prepare or modify it for being assimilated to, and appropriated by, the various organs of the body, or, in other words, for being converted into blood.

The general expression, "function of digestion," includes several minor or subordinate processes. According to Milne Edwards, the acts of the digestive function may be classed as follows: 1. There is the prehension of the food; 2. Its mastication; 3. Its insalivation; 4. Its deglutition; 5. Its chymification or stomachal digestion; 6. Its chylicification or intestinal digestion; 7. Defecation; and 8. The absorption of the chyle.

Before examining these acts in succession, and the mechanism by which each is effected, we must have clear conceptions regarding the classification of food, the quantity of food, and other allied subjects, which are discussed in the article DIET; and we should likewise have some knowledge of the causes of those sensations which we call *hunger* and *thirst*, which are, or ought to be, our natural guides regarding the periods for taking food, and the quantity to be taken. The immediate cause of ordinary hunger cannot be explained; but that it is due to some peculiar condition of the gastric mucous membrane, seems probable from the fact, that the sensation continues after division of the pneumogastric nerves, from which the stomach mainly derives its nervous fibers, if we correctly interpret the feelings of the animals on which the experiments were made. In extreme hunger, the sufferer complains of a sense of sinking, which is referred to the region of the stomach, while general faintness and sometimes considerable pain are present. Hunger, or the want of food which occasions it, may be diminished by rest, sleep, or any cause that retards the general change which is perpetually going on in all the tissues of the body. We have shown in the article DIET, that tobacco and alcohol have a power of limiting the disintegration of the tissues, and thus of keeping off or diminishing hunger. When the sensations of extreme hunger are not relieved by food, the body begins to feed upon its own tissues, and the symptoms of starvation (q.v.) begin to manifest themselves. The period at which death occurs from abstinence, varies greatly in different animals—young animals always dying sooner than older ones. In man, total privation of food usually causes death in about a week; but if a little drink be allowed, life is considerably prolonged.

Thirst is dependent upon a peculiar condition (probably undue dryness) of the mucous membrane of the upper part of the digestive tube. The thirst in febrile affections is, however, probably due to the morbid state of the blood.

We now proceed to the consideration of the different acts of which the digestive function is made up.

1. In the act of prehension, man and many of the lower animals (monkeys, squirrels, etc.) employ the hands or anterior extremities and mouth; the lips and anterior teeth, and, to a certain extent, the tongue, being also employed in this function. In the lower animals, however, the modes of prehension are various. Some (like the giraffe) twist the tongue around the leaves and young branches of trees; others (the ant-eaters) have a remarkably long tongue, covered with a viscid secretion, and by thrusting this organ into ant-

hills, etc., secure their prey; and in the chameleon among reptiles, and the woodpecker among birds, the tongue seems specially developed for prehensile purposes. In the elephant, this act is accomplished by the prolongation of the nostrils into the organ popularly known as the trunk. In other mammals (the ruminants and solipeds), the large pendulous lips are the organs employed. In birds, the bill (which is a modification of the lips) is always the prehensile organ of that class.

The prehension of fluids is effected in two ways: sometimes the liquid is poured into the mouth, and is allowed to fall into it by its own weight; in other cases, the tongue is used after the fashion of a piston, being drawn within the mouth so as to exhaust the anterior part of that cavity, and fluids are thus forced to enter by atmospheric pressure.

2. Mastication is effected in the cavity of the mouth by means of the teeth. This cavity is bounded superiorly by the palate or roof of the mouth, and in other directions by the cheeks, lips, and tongue. Projecting into its interior, above and below, is an arched series of teeth, which are firmly fixed by roots into corresponding sockets in the upper and lower jawbones. The upper jaw (and consequently the dental arch imbedded in it) is immovable, or only movable with the entire head; but the lower jaw, with its teeth, is capable of moving upwards, downwards, backwards, forwards, and laterally, by means of the powerful muscles of mastication. It is by the varied movements of the lower teeth against the upper, through the action of these muscles, that the food is broken down or masticated. For information regarding the structure, etc., of the teeth, see **TEETH**; see also **DENTITION**.

The operation of mastication is very important, since the more the food is broken down the more easily will it mix with the saliva and other fluids which participate in the digestive process.

3. Insalivation is effected by the admixture of the secretions of the three pairs of salivary glands (the parotids, the submaxillaries, and the sublinguals) and of the buccal mucus with the triturated food. A brief description of these structures is given in the article **GLAND**. The common saliva, formed by the combined secretion of these various secreting organs, is a colorless, turbid, viscid, inodorous, and tasteless fluid, which, after standing for some time, deposits a layer of pavement epithelium (see **EPITHELIUM**) and mucus corpuscles. In the normal state, its reaction is alkaline, but the degree of alkalinity varies, and is greatest during and after meals. Saliva does not contain more than five or six parts of solid constituents to 995 or 994 parts of water, the most important ingredients being an organic matter termed *ptyaline*, and sulphocyanide of potassium, neither of which substances occurs in any other solid or fluid of the body. The daily quantity of saliva secreted by an adult man is estimated at about 48 ounces, but determinations of this kind must be regarded only as approximations to the truth, since the activity of the salivary glands is dependent upon various influences and conditions. Thus, movement of the lower jaw, as in masticating, speaking, or singing, increases the secretion; as also do acrid and aromatic substances, and dry hard food; while the use of moist and soft food is accompanied by a scanty secretion.

The uses of the saliva in reference to digestion are partly mechanical and partly chemical. The mechanical uses are almost too apparent to require notice. The moistening of the dry food by the saliva serves the double purpose of adapting it for deglutition and of separating the particles, and thus allowing them to be more freely acted on by the other digestive fluids; moreover, from its viscosity, it lubricates the bolus of food, and thus facilitates deglutition; and it is probably also subservient to the sense of taste. The great chemical use of the saliva is to convert the amylaceous (or starchy) portion of the food into glycose or grape sugar, and thus to promote its absorption.

4. Deglutition is the act by which the food is transferred from the mouth to the stomach. The pharynx, or cavity into which the mouth leads, takes so slight a part in the digestive process, that we need scarcely allude to any anatomical details connected with it. It is sufficient to observe that between it and the mouth is the pendulous or soft palate, which is a movable muscular partition that separates the two cavities during mastication. As soon, however, as the latter act is accomplished, and the bolus is pressed backwards by the tongue, the soft palate is drawn upwards and backwards, so as to permit the passage of the food into the pharynx. The bolus or pellet of food, having arrived near the esophagus or gullet (which is continuous inferiorly and posteriorly with the pharynx), is driven into it by the action of certain muscles, which almost surround the pharynx, and are termed its *constrictor* muscles. All voluntary action ceases as soon as the food is pressed backwards by the tongue into the pharynx. It is impossible to recall the pellet, and it is necessarily carried on (without even our cognizance) into the stomach. On receiving the food forced into its upper extremity by the action of the constrictor muscles of the pharynx, the esophagus is dilated (for it usually lies in a collapsed state, with its walls in contact, or nearly so); this contact of the pellet with its mucous membrane causes its muscular walls to contract, and the food is thus driven, by a series of these contractions, into the stomach. The act of deglutition is now completed.

5. Stomachal digestion or chymification is the next process to be considered. The whole of the alimentary canal (q.v.), (fig. 1) below the diaphragm (q.v.), or great muscular partition which separates the cavity of the chest from that of the abdomen or belly,

possesses the following points in common, in relation to structure: The stomach, the small intestine, and the large intestine, are all lined by mucous membrane, have a muscular coat, consisting of two sets of distinct fibers—namely, circular fibers which surround the tube or viscus after the manner of a series of rings, and longitudinal fibers running in the same direction as the intestine itself—and are invested with a serous membrane, the peritoneum (see **SEROUS MEMBRANES**), which at the same time retains the viscera in their proper position, and permits their necessary movements.

The human stomach is an elongated curved pouch, lying almost immediately below the diaphragm, and having the form of a bagpipe. It is very dilatable and contractile, and its function is to retain the food until it is duly acted upon and dissolved by the gastric juice, which is secreted by glands lying in its inner or mucous coat, and then to transmit it, in a semi-fluid or pulpy state, into the duodenum. Its average capacity is about five pints. The parts of it which have received special names are the greater curvature (fig. 1) *b*, the lesser curvature, upon its upper border, and the cardiac, *c*, and pyloric, *d*, extremities.

The mucous membrane, or lining coat of the stomach, is thick and soft, and lies in irregular folds, in consequence of the contraction of the muscular coat, unless when the organ is distended with food. On opening the stomach, and stretching it so as to remove the appearance of folds, we perceive even with the naked eye, but better with a lens, numerous irregular pits or depressions, irregular in shape, and averaging about  $\frac{1}{300}$ th of an inch in diameter. To see them properly, the mucus with which they are filled must be washed out (fig. 2, A). These pits are so shallow as not to dip into the mucous membrane to a greater extent than  $\frac{1}{4}$ th or  $\frac{1}{3}$ th of the thickness. The rest of the thickness is chiefly made up of minute tubes, running parallel to one another, and vertically to the surface of the stomach (fig. 2, B). These are the gastric tubes or glands which secrete the gastric juice from the blood in the capillaries which abound in the

B, stomach-tube from the middle of the human stomach, magnified about 150 diameters: *a*, wall of the tube, lined with large oval nucleated cells; *b*, the same cells isolated; *c*, nucleated cells of columnar epithelium, occupying the upper parts of the tubes; *d*, blind extremity of the tube.

mucous membrane. They pass in twos, threes, or fours from the bottom of each pit, and usually subdivide into several tubes, which, after running a more or less tortuous course, terminate in blind or closed extremities. These tubes are filled with epithelial cells, whose contents are composed of granules, with which oil-globules are often mixed, and each tube is invested with capillaries, which usually run in the direction of its long axis. In the pyloric or duodenal end of the stomach, these tubes (at least in the dog and several other animals whose stomachs have been carefully examined in a perfectly fresh state) are considerably wider than those which we have described, and differ from them also in other respects; and hence some physiologists believe that while they collectively secrete the gastric juice, one set may secrete the acid fluid and the organic matter

termed pepsine, and the other mucus; the free acid and the pepsine are, as we shall shortly see, the two essential constituents of the gastric juice.

When food is introduced into the stomach, three special phenomena are induced in that viscus: 1. There are certain movements induced which are dependent on its muscular coat; 2. The mucous membrane is altered in appearance; and 3. There is the secretion of the gastric juice. Each of these phenomena requires a brief notice.

On killing an animal while the act of digestion is going on, and at once laying open its abdomen, we find that the stomach is in a contracted state, firmly embracing its contents, and with both its orifices so closed as to prevent the escape of the food, this contraction being due to the stimulation of the muscular coat by the food. If we examine the movements of the stomach during digestion, which we can do either by exposing the stomach of a living animal, or by sending a magneto-electric current through this organ in an animal just killed, we perceive that, in the cardiac half or two thirds, the movements are extremely slow, the muscular coat apparently contracting on the food, and progressively sending it towards the pylorus; whilst in the pyloric end of the stomach the movements are more energetic and rapid, resembling the peristaltic or vermicular movement, which we shall presently describe as occurring in the intestinal canal. When the transverse constriction has reached the firmly shut pylorus, a relaxation lasting about a minute ensues, followed by a repetition of the circular contractions. The movements which these contractions impress upon the food are described by Dr. Beaumont in the following terms: "The food entering the cardiac end of the stomach, *c*, turns to the left, descends into the splenic extremity, *s*, and follows the great curvature towards the pyloric end, *d*. It then returns in the course of the smaller curvature, and makes its appearance again at the cardiac aperture in its descent into the great curvature to perform similar revolutions. These revolutions are effected in from one to three minutes." This account, given by Dr. Beaumont, is based on the observations which he made in the stomach of Alexis St. Martin, a Canadian, with a fistulous opening into the stomach, whose case is referred to in the article DIET. Dr. Brinton, however, adopts a modified view, which is probably the correct one. He supposes that the semi-fluid food entering at *c* (fig. 3), the cardiac orifice, goes in the directions marked *a*, partly along the greater and partly along the lesser curvature; and that these two currents of food meet at the closed pylorus, when they are both reflected into the direction *b*, forming a central or axial current, occupying the real axis of the stomach which unites the two apertures. The mutual interference of these currents at their borders causes a uniform admixture of the various substances composing them, while the reflection of the upper and lower currents into one another insures an equal contact of all the mass with the secreting surface of the mucous membrane.

The changes in the mucous membrane are mainly the following: The inner surface of the healthy fasting stomach is of a paler pink tint than after the introduction of food, and while in the latter case the reaction of the moisture on the surface is very acid, in the former it is neutral, or even alkaline. Dr. Beaumont found (in the case of Alexis St. Martin) that, on the introduction of food into the stomach, the vessels of the mucous membrane became more injected, and that its color became changed from a pale pink to a deep red. A pure colorless and slightly viscid fluid, with a well-marked acid reaction, was then observed to distill from the surface of the membrane, and to collect in drops, which trickled down the walls, and mixed with the food.

That the *gastric juice*, which is the term applied to the acid fluid which Dr. Beaumont saw exuding from the mucous membrane, and which is secreted or formed in the gastric tubes which we have already described, is capable of exerting a solvent action on food, is proved by numerous experiments. It was first ascertained by Reaumur (1752), who obtained some of this fluid by making animals swallow sponges with a string attached, by which he could withdraw them. He thus showed that alimentary substances out of the body were altered by this fluid in the same manner as they are changed in the stomach, and disproved the favorite theory of that period, which ascribed all the changes which the food underwent in the stomach to a species of trituration. The subject of *artificial digestion*, or digestion out of the body, has, since that period, been carefully investigated by many observers, and there is now no doubt that the changes which the food undergoes in the stomach are essentially chemical, and not mechanical.

Two years before Beaumont's experiments, Dr. Prout had ascertained not only that an acid fluid is secreted by the gastric mucous membrane of rabbits, hares, horses, dogs, etc., during digestion, but that the acid is the muriatic or hydrochloric acid, and it was supposed that the solvent action of the gastric juice was due to this source. But experi-

*aa*, the hemispherical or surface current, carrying the semi-fluid food towards the closed pylorus, where it is reflected into *b*, the central current, which unites the cardiac (*c*) and pyloric (*d*) openings.

ments showed that the solvent action is not due simply to the acid of the gastric juice, and that the latter must contain some other ingredient which, either alone or in combination with the acid, can exercise this power. It was then discovered that the addition of a portion of the gastric mucous membrane to water acidified with hydrochloric acid produced a perfect digestive fluid, due attention being paid to the temperature, which should be kept at about 100°, or about the normal temperature of the interior of the animal body. Later observations showed that we can obtain from the gastric mucous membrane the special organic matter on which its digestive power depends, and to this substance the name of *pepsine* has been given. The two essential elements of the gastric juice are then: 1. A free acid, which in some cases seems to be hydrochloric alone, and in others a mixture of hydrochloric and lactic acids; and 2. An organic matter, which is found on analysis to be highly nitrogenous, and to be allied to the albuminates, and which we term pepsine. The best analysis of human gastric juice is that made by Schmidt of Dorpat, who, in 1853, had an excellent and rare opportunity of examining it in the case of an Esthonian peasant, Catharine Kütt, aged 35 years, and weighing about 118 lbs., in whom there had existed for three years a gastric fistula or opening, three or four lines in diameter, under the left breast, between the cartilages of the ninth and tenth ribs. The introduction of dry pease and a little water into the stomach, through the opening, occasioned (even in the morning, on an empty stomach) the secretion of from 5 to 7 ozs. of a clear limpid fluid with an acid reaction, which, however, was much less strong than Schmidt had observed in previous experiments on the gastric juice of dogs and sheep, in which he had artificially established similar fistulous openings. The following table gives the mean of two analyses of the gastric juice of Catharine Kütt, with corresponding mean results of the same fluid in the sheep, a purely herbivorous animal, and in the dog, a purely carnivorous animal.

	Human Gastric Juice.	Sheep's Gastric Juice.	Dog's Gastric Juice.
Water.....	994.40	986.15	971.17
Solid constituents.....	5.60	13.85	28.83
Pepsine.....	3.20	4.20	17.51
Hydrochloric acid.....	0.20	1.56	2.70
Chlorides of sodium, etc.....	2.08	6.00	5.88
Phosphates.....	0.12	2.09	2.74

The only impurity that could affect these analyses, is the saliva that possibly might have been swallowed.

The quantity of the gastric juice secreted in 24 hours was determined by Bidder and Schmidt (*Die Verdauungs-säfte*, etc.) in the sheep to be  $\frac{1}{4}$ th, and in the dog  $\frac{1}{10}$ th of the weight of the body. If the latter ratio were true for men, a man of ten stone weight would secrete about 14 lbs. of this fluid daily. In the case of Catharine Kütt, the mean daily quantity amounted to no less than 31 lbs., or to more than a fourth part of the weight of her body. On this calculation, a man of ten stone would daily secrete 37 lbs. of gastric juice.

The uses of this fluid in reference to digestion are clear. It serves not only to dissolve, but also to modify the nitrogenous elements of the food (such as albumen, fibrin, casein, and, in short, all animal food except fat, and the blood-forming portion of vegetable food), converting them into new substances, termed *peptones*, which, although they coincide in their chemical composition, and in many of their physical properties, with the substances from which they are derived, differ essentially from them in their more ready solubility in water, and in various chemical relations. Thus, albumen is converted by the gastric juice into albumen-peptone, fibrin into fibrin peptone, etc. According to the investigations of Meissner, the albuminates are simultaneously decomposed or broken up into peptones and substances which he terms *parapeptones*, which latter are not further changed by the action of the gastric juice, but are converted into peptones by the action of the pancreatic juice, with which they come in contact in the duodenum.

All the best observers agree that the gastric juice exerts no apparent action on the non-nitrogenous articles of food—namely, the fats and the carbo-hydrates (sugar, starch, etc.); as, however, the fats exert a favorable influence on the digestion of nitrogenous matters, it is probable that they undergo some slight, although not appreciable, modification. Gelatine and the gelatinous tissues are, as far as is known, the only nitrogenous articles of food which are not converted into peptones and parapeptones by the action of the gastric juice.

Although the main object of the gastric juice is to dissolve the albuminates, etc. (e.g., the contents of the egg, flesh, cheese, etc.), it appears from the experiments of Lehmann, Schmidt, and others, that it cannot dissolve the quantity necessary for the due nutrition of the organism. According to Lehmann, gastric juice can only dissolve  $\frac{1}{10}$ th of its weight of coagulated albumen, while Schmidt makes the quantity as low as  $\frac{1}{15}$ th. Now, since a dog secretes about  $\frac{1}{10}$ th of its weight of gastric juice daily, it would only be able—even taking Lehmann's estimate, which is more than twice as high as Schmidt's—to digest 5 parts of dry or coagulated albumen for every 1000 parts of its

weight; but a dog, in order to keep in condition on an exclusive flesh diet—and this is its natural food—should take 50 parts of flesh, containing 10 parts of dry albuminates, for every 1000 parts of its weight. Hence its gastric juice only suffices for the digestion of half the albuminates necessary for nutrition—a result which is in accordance with the observed fact, that a considerable portion of the albuminates enters the duodenum in an undissolved state, and which will be explained when we consider the part which the intestinal juice—the fluid secreted by the various glands lying in the mucous membrane of the small intestine—takes in the digestive process. On comparing the experiments made on dogs with those made on Catharine Klitt, it appears that in the human subject the gastric digestion of the albuminates is much more imperfect than even in the dog.

FIG. 4.

The under surface of the stomach and liver, which are raised to show the duodenum and pancreas.

st, stomach; p, its pyloric end; l, liver; g, gall-bladder; d, duodenum, extending from the pyloric end of the stomach to the front, where the superior mesenteric artery (sm) crosses the intestines; pa, pancreas; sp, spleen; a, abdominal aorta.

The process of gastric digestion is slow. According to Beaumont's researches on Alexis St. Martin, the mean time required for the digestion of ordinary animal food, such as butcher's meat, fowl, and game, was from two hours and three quarters to four hours.

The next point to be considered is: What becomes of the matters that are thoroughly dissolved in the stomach? Are they absorbed, without passing further down the canal? or do they pass through the pyloric valve into the duodenum, and are they finally taken up by the lacteals? Two of our highest authorities in physiological chemistry, Frerichs and Donders, maintain that the absorption of the peptones commences in the stomach; but the view generally adopted is, that the albuminates, etc., which are converted into peptones, are for the most part taken up by the lacteals. The rapidity with which

FIG. 5.

aqueous solutions of iodide of potassium, the alkaline carbonates, lactates, citrates, etc., pass into the blood, and thence into the urine, saliva, etc., shows that the absorption of fluids must take place very shortly after they are swallowed, and there is little doubt that the blood-vessels (capillaries) of the stomach constitute the principal channel through which they pass out of the intestinal tract into the blood. As the veins of the stomach, which are formed by the union of these capillaries, contribute to form the portal vein (see CIRCULATION, ORGANS OF), the absorbed matters pass directly to the liver, and probably stimulate it to increased secretion (fig. 4).

6. We must now follow the progress of the semi-fluid mass known as the *chyme*, from the stomach into the small intestine, and notice the changes which are collectively impressed upon it, and are known as *chylification* or intestinal digestion. But before

FIG. 6.

Two villi, denuded of epithelium, with the lacteal vessels in their interior.

a, limbary membrane of the villus; b, basis of the same; c, dilated blind extremity of the central lacteal; d, trunk of the same.

we can satisfactorily do this, we must say a few words regarding the intestinal mucous membrane, with its various glands, etc., and on the changes which take place in it during digestion.

The mucous membrane of the small intestine resembles that of the stomach in so far as it is of considerable thickness, and consists in a great measure of laterally grouped tubes. The reader is referred to fig. 5, which exhibits a section of the mucous membrane of the small intestine in the dog. These tubes, which form the great mass of the middle portion of the section marked *b*, are commonly called the *follicles of Lieberkuhn*, although they were first described by Brunner. They are straight, nearly uniform in diameter throughout their entire length, and are parallel to one another, and perpendicular to the inner surface of the small intestine on which they open. Nothing is known of the exact nature of their secretion; but in association with the secretions of other glands, they combine to yield the intestinal juice whose characters and uses will shortly come under our notice.

The projecting bodies marked *a* in the figure are termed the *villi*; they are minute processes of the mucous membrane of the small intestine, and obviously serve to increase to a great extent the amount of absorbing mucous membrane. They first appear in the duodenum, where they seem to develop themselves as elongations of the partitions between the cells or pits into which the tubes open. Comparatively scanty in number at first, they become very numerous (covering the whole surface) in the further part of the duodenum and the rest of the small intestines, giving to the mucous membrane a velvet-like or pilous appearance; they finally cease at the ileo-cæcal valve, which forms the boundary between the small and large intestine. In man, they are conical in shape, and measure from  $\frac{1}{4}$ th to  $\frac{1}{10}$ th of an inch in length. They vary much in shape and size in the lower mammals and in birds. (In carnivorous animals, as the dog, they are longer and more filiform than in man.)

The structure of a villus (fig. 6) is somewhat complicated, but we must endeavor to explain it, because, without tolerably accurate knowledge on this point, no one can understand how most of the essential elements of food (the albuminates and fatty matters) make their way from the intestine to the blood. Each villus is provided with an abundant set of capillaries, which doubtless absorb fluid matters, which thus find their way directly from the bowels into the blood (fig. 7). A single artery enters its base, and passing up its center, divides into a capillary plexus, which almost surrounds the villus immediately beneath the mucous membrane. From these arise small veins, which usually pass out of the villus in two, three, or more trunks, and contribute to form the portal vein. See CIRCULATION.

FIG. 7.

Vertical section of the coats of the small intestine, showing the capillaries and the beginnings of the portal vein. The arteries are not seen, not having been penetrated by the injection which has been thrown into the portal vein.

*a*, vessels of the villi; *b*, those of the tubes or follicles of Lieberkuhn; *c*, those of the muscular coat.

There is abundant evidence that the function of the villi is connected with absorption, and mainly with the absorption of chyle. 1. The villi exist only in the small intestine, where the absorption of food goes chiefly on. 2. They are most developed in that part of the intestine where chyle is first formed. 3. They are turgid, enlarged, and opaque during the process of chylification, and small and shrunken in animals that have been kept fasting for some time before death.

In addition to the villi, the mucous membrane of the small intestine presents numerous transverse folds, which are termed the *valvule conniventes*, from their valvular form and from their movements under water resembling the winking motion of the eyelids (fig. 8). Each fold passes round three fourths or more of the gut; and in the lower part of the duodenum, and in the jejunum (the parts in which they are most fully developed) they are often more than half an in. in depth; further on, they diminish in depth, length, and number, and in the lowest part of the ileum they can scarcely be traced. Their object clearly is to increase the extent of the absorbent mucous membrane.

In addition to Lieberkuhn's follicles or tubes, which exist in the whole of the smaller intestine, there are other glandular or secreting structures, imbedded in the submucous tissue of certain portions of the intestinal tract, which require consideration. These

are: 1. Brunner's glands, which occur only in the duodenum; 2. Solitary glands, which seem to occur in all parts of the intestine, both small and large; and 3. Peyer's glands, which are usually confined to the ileum.

*Brunner's glands* are most abundant at the pyloric end of the duodenum. In structure, they resemble the pancreas, their ultimate elements being bunches of vesicles, from which minute ducts arise, which coalesce and form larger ducts, through which the secretion is poured into the duodenum. It is believed that they secrete a fluid similar to the pancreatic juice. The *solitary glands* occur in all parts of the intestine, but are perhaps more numerous in the jejunum than elsewhere. Each gland is a simple membranous flask-shaped vesicle, the neck corresponding to the surface of the intestine, while the rounded base lies in the submucous tissue. The neck presents no opening, and how the contents, which consist of nuclei and granular particles, are discharged into the intestine, is not clearly known. As we never see them larger than a mustard-seed, we may presume that, on attaining that size, they burst. *Peyer's glands* (fig. 9) are apparently mere aggregations of solitary glands, forming oval patches in the ileum. These patches vary in size and number, being largest towards the cæcum, where their long diameter sometimes measures 3 or 4 in., and smallest towards the jejunum; while their number varies from 15 to 20, or even more. Nothing certain is known regarding the uses of these solitary or aggregated glands; but as they are largest during the digestive process, we must infer that they are in some way connected with that function. Possibly the peculiar odor of the feces may be due to their secretion. In typhoid or enteric fever, and in phthisis, these glands become ulcerated, which probably occasions the diarrhea so common in these diseases.

Brunner's glands are much more developed in the herbivora than in the carnivora; Peyer's, on the other hand, are most developed in the latter.

We have endeavored, in the preceding sentences, to give the reader some idea of the complicated structure of the mucous and submucous coat of the small intestines; we now proceed to notice the chief uses of the muscular coat of the intestine. This coat,

FIG. 8.

Small intestine distended and hardened by alcohol, and laid open to show the valvulae conniventes.

FIG. 9.

Vertical section through a patch of Peyer's glands in the dog. *a*, villi; *b*, tubes of Lieberkuhn; *c* submucous tissue, with the glands of Peyer imbedded in it; *d*, muscular and peritoneal coats; *e*, apex of one of the glands projecting among the tubes.

as has been already mentioned, consists of two layers of muscular fibers—namely, circular and longitudinal fibers, of which the former lie next to the submucous coat. The peristaltic or vermicular action by which the substances which enter the duodenum from the stomach are moved onwards, is due to this muscular coat. A person who has once seen the abdomen of an animal laid open immediately after death, will have a better idea of the nature of this movement than can be afforded by any description. It commences about the pyloric third of the stomach, from whence successive wave-like movements are propagated through the entire length of the intestinal canal. It is the rapid succession of these alternate contractions and relaxations that impels the intestinal contents onwards, and occasion those movements which, from their resemblance to the writhings of a worm, have been termed *vermicular*. It is very probable that the rapidity of this movement varies in different individuals—those persons, for example, whose bowels act twice daily having a more rapid vermicular motion than those in whom the act of defecation occurs only once in the twenty-four hours.

We have now to consider the effects produced on the chyme by the different fluids with which it becomes mixed in the small intestine. These fluids are: 1. The bile; 2. The pancreatic juice; and, 3. The intestinal juice.

The bile (see BILE) is a faintly alkaline or neutral fluid, containing two essential constituents, one of which is of a resinous nature, while the other is a pigment. The resinous constituent is not precisely identical in all kinds of bile, but it generally consists of a soda-salt whose acid is either glyco-cholic or tauro-cholic acid (q. v.), or of a mixture

of these salts. Strecker, to whom we are mainly indebted for our knowledge of the chemistry of the bile, states that in most mammals the resinous constituent merely differs in the varying proportions in which the taurocholates and glycocholates are intermixed, the former usually preponderating. According to Lehmann, the resinous constituent amounts to at least 75 per cent of the solid residue. The bile-pigment occurs in the bile of different animals under two forms—namely, as a brown and as a green pigment, the latter probably only differing from the former in being more highly oxidized. There has never been a case in which physiologists have had an opportunity of directly observing the quantity of bile that is secreted by the human subject, and all our information on this subject is derived from observations on animals, in which the *ductus choledochus communis* (see LIVER) has been tied, and a fistulous opening established into the gall-bladder. If the same proportion of bile to bodily weight holds good in man as in the dog, a man weighing ten stone would secrete daily about five pounds of bile. All observers agree, that the amount of the biliary secretion varies directly with the quantity of food; and as animals with biliary fistulae (in whom all the bile escapes externally, instead of making its way into the duodenum) usually have voracious appetites, experiments on this point are easily made. There is great discrepancy of opinion as to how soon after a meal the bile flows most abundantly into the intestine. According to Kölliker and Müller, whose experiments were made on dogs fed only once a day, very little bile is secreted in the first and second hour after a meal, more in the third, fourth, and fifth; the maximum being sometimes attained in the fifth, sometimes not till the eighth hour.

Numerous and somewhat discrepant views have at different times been advanced regarding the functions of this fluid; we shall here only notice those functions which are connected with digestion. One use that has been ascribed to it, is to neutralize in the small intestine the acid chyme which emerges from the stomach. But the bile can contribute little or nothing to the neutralization of the free acid, because, in the first place, the bile is very slightly alkaline, and often perfectly neutral; and secondly, because the chyme in the intestine is still acid after the admixture of the bile. Again, the bile has been asserted to possess a special solvent action on the chyme; but none of the ordinary constituents of the latter seem to be essentially changed, even when digested for a long time with fresh bile. Again, much importance has been attached to the antiseptic action of the bile on the contents of the intestinal canal, in favor of which view it is alleged that when no bile is poured into the intestine, the fæces have a putrid odor, as is sometimes observed in patients with jaundice, and as was noticed by Frerichs in animals in which the *ductus choledochus* had been tied. Another use that has been assigned to the bile is, that it exerts a stimulating action on the intestinal walls, and thus acts as a natural purgative; and in support of this view, it may be mentioned that jaundice (in which the bile does not flow into the intestine) is often accompanied by extreme constipation, and that purified ox-gall, taken either in the form of pill or enema, produces an undoubted purgative action. But the main use of the bile seems to be to promote the digestion of fatty matters, and it accomplishes this end not so much by any solvent chemical action on the fats (which at most is extremely slight), as by a peculiar physical action both on the fats and on the intestinal walls, disintegrating the former, and impressing on the latter (by moistening the villi) a peculiar condition which singularly facilitates the absorption of fatty matters. This view is fully confirmed both by direct experiments out of the body, and by comparing the relative qualities of fat that are retained in the body and applied to the purposes of life by animals with biliary fistulous openings, and by healthy animals.

The pancreatic fluid which is poured into the duodenum at the same spot with the bile (see fig. 1), is a colorless, clear, somewhat viscid and ropy fluid, devoid of any special odor, and exhibiting a strong alkaline reaction. This fluid, as yielded by different dogs with permanent fistulous openings, varies considerably in chemical composition; the collective solid constituents ranging from 1.5 to 2.3 per cent, the organic matters from 0.9 to 1.6, and the mineral matters from 0.62 to 0.75.

The most abundant and important of the solid constituents is a peculiar substance termed *pancreatine*, or pancreatic diastase or ferment, in combination with soda, to which this fluid owes its principal chemical and physiological properties. Calculating from the quantity of pancreatic juice secreted by dogs of known weight, we may infer that a man weighing ten stone secretes daily about ten ounces of this fluid.

One of the chief uses of the pancreatic juice in relation to digestion, is to convert into sugar the amylaceous or starchy matters which have escaped the action of the saliva, and have passed unchanged into the duodenum. It possesses this property in a far higher degree than the saliva; and, as might be expected in reference to this use, the pancreas is found to be much more developed in herbivorous than in carnivorous animals. Bernard, the representative of the modern school of physiology in France, claims for this fluid another important function; he believes that he has proved that it is solely by the action of this secretion that the fat is reduced to a condition in which it can be absorbed and digested; that is to say, that it is decomposed into glycerine and a fatty acid. See FATS. This view, has, however, not been generally accepted, and it seems probable that although the change described by Bernard takes place when fat and pancreatic juice are simply mixed together in a test-tube, it does not actually

take place in the intestine, the acid gastric juice probably acting as an interfering agent. An attempt has lately been made by Corvisart and Meissner to prove that, like the gastric juice, this fluid can dissolve albuminous matters; but this view cannot be substantiated. Considering the large quantity of pancreatic fluid which is yielded in 24 hours, Schmidt, who has made the digestive juices the subject of his special study, is of opinion that the function of this fluid is not so much to promote the conversion of starch into sugar, as for the purpose of diluting the chyme, and for reconvertng the soda (which in the pancreas has been separated from the chlorine of the chloride of sodium, and has combined with the pancreatine) into chloride of sodium. He shows, from numerical calculations, that more than half of the chloride of sodium existing in the blood which circulates through the pancreas, is broken up into hydrochloric acid and soda, of which the former is separated by the gastric glands, while the latter unites with the pancreatine. Meeting again in the duodenum, the hydrochloric acid and the soda reunite, and re-form chloride of sodium, which is again absorbed, and re-enters the circulation. This is perhaps one of the most singular decompositions and reunions occurring in the animal body.

Of the last of the fluids poured into the intestine, and co-operating in the digestive process, the *intestinal juice*, we know comparatively little. It is the aggregate secretion of the various glands which we have described as occurring in the walls of the small intestine. It is a colorless, or sometimes yellowish, ropy, viscid fluid, which is invariably alkaline. We are not aware of any special or characteristic constituent in it, such as occurs in the other chylipoietic fluids. Its daily quantity is probably nine or ten ounces. It seems to unite in itself the leading properties of the pancreatic and gastric juices; that is to say, it resembles the former in converting starch into sugar, and the latter in dissolving flesh and other albuminous bodies.

We shall conclude this part of the subject with a few remarks on the chemical composition of the contents of the small intestine. On laying open the gut, we usually find a semi-solid admixture of imperfectly digested and indigestible substances and of the constituents of the digestive fluids in a more or less changed condition. The reaction of this mass varies in different parts of the canal, and in some measure with the nature of the food. Thus, the contents of the stomach always redden litmus paper, whatever kind of food has been taken; the duodenal contents are also always acid, but in a far less intense degree; in the jejunum we meet with only a faint acid reaction, which altogether disappears in the ileum; while in the cæcum, and sometimes in the lower part of the ileum, an alkaline reaction occurs. After a purely flesh diet the acid reaction disappears shortly below the duodenum, while, after the sole use of vegetable food, it may sometimes be traced even to the cæcum. As a general rule, the contents of the large intestine are alkaline.

In consequence of the rapid absorption that goes on along the intestinal surface, we meet with a comparatively small amount of soluble matters in these contents. Among these soluble matters we often find glucose (or grape-sugar), which seems to owe its origin to the metamorphosis of starch, and not to sugar having been present in the food; for after saccharine food has been taken, we rarely meet with it in any quantity in the small intestine, its absorption taking place with great rapidity. In the alcoholic extract of these contents we can almost always find evidence of the presence of biliary constituents. In the duodenum, and for a little way beyond it, we find glycocholic and taurocholic acid; descending a little further, they rapidly diminish, till we find the products of their disintegration; while in the large intestine, little more than a trace of these products can be detected. These chemical observations confirm the experiments of Schmidt, which show that nearly half the bile which is poured into the duodenum is decomposed before it reaches the middle of the small intestine.

We have now arrived at the seventh stage of the digestive process, that of *defecation*. The line of demarcation between the small and large intestine is very obvious, and by the peculiar arrangement of the ileo-cæcal valve (see fig. 10), matters are allowed to pass forward with facility, while regurgitation is impossible. For anatomical details regarding the large intestine, we may refer to the articles ALIMENTARY CANAL, CÆCUM, and COLON. The contents of the large intestine differ very materially from those which we have been considering in the last paragraph, and constitute the faeces. They are more solid and homogeneous, and are often molded into a definite shape by the cells of the colon. The only essential change which the contents undergo in this part of their course is, that they increase as they pass onward in solidity, in consequence of the absorption of fluid from them by the mucous membrane. They are propelled forward

FIG 10.

Cæcum inflated, dried, and opened to show the arrangement of the valve.

a, termination of the ileum; b, ascending colon; c, cæcum; d, a transverse constriction projecting into the cæcum; e, f, lips of the valve separating the small from the large intestine; g, the vermiform appendix of the cæcum.

into the rectum by the vermicular action which has been already described. Here they accumulate, being prevented from escaping by the contraction of the sphincter muscle—a band of strong muscular fibers surrounding and closing the gut at its lower extremity. The act of defecation, or of expulsion of the feces from the rectum, is effected partly by the muscular fibers of that part of the intestine which are stimulated to contraction by a certain degree of distension, and which are to a certain extent under the influence of the will, and partly by the simultaneous contractions of the abdominal muscles and of the diaphragm, which, by reducing the antero-posterior and transverse diameters of the abdominal cavity, compress the intestinal canal in such a manner as greatly to assist the expulsive action of the rectum. These forces, or some of them (for usually the detrusive action of the muscular fibers of the rectum is sufficient), overcome the passive contraction of the sphincter, and the act of defecation is the result.

The feces consist of a mixture composed of undigested particles of food (such as vegetable cellular tissue, fragments of tendon, skin, and half-digested muscular fiber), of epithelium and mucus (derived from the intestinal walls), and of traces of decomposed biliary matters. Their peculiar odor is ascribed by some to the secretion of Peyer's glands, and by others to decomposed bile; while Liebig refers it to a decomposition of albuminous matters, founding his view upon the fact, that by burning albumen with potash, he could manufacture in the laboratory odors of a fecal character. The last is the least probable view. Their color varies with the food. On a mixed diet, they are of a yellowish-brown tint; on a flesh diet, much darker; and on a milk diet, quite yellow—and they become darker on exposure to the air. Their reaction is most commonly but not invariably alkaline. Their daily quantity is very variable; the mean of 17 observations made by a German physiologist, Wehsarg, was about 4.6 ounces, of which very nearly one ounce was solid matter, the rest being water; the largest and the smallest quantities being ten, and rather more than two ounces. Liebig, many years ago, made the observation that the insoluble salts of the food are mainly carried off by the feces, while the soluble salts are for the most part eliminated by the urine. For further details on the chemistry of this subject, we must refer to the elaborate Memoirs of Dr. Marcet, published in the *Philosophical Transactions*.

8. The absorption of the chyle forms the completion of the digestive act. The coats of the intestines contain two perfectly distinct sets of vessels—one through which blood circulates, and the other containing a milky or transparent fluid, chyle or lymph, which, after a somewhat circuitous route, is poured into the blood. We have already referred to the fact, that fluids are absorbed from the stomach and intestine by the veins and capillaries of the mucous membrane; we now proceed to notice the mode in which the vessels of the second kind, the lacteals, act as absorbing agents. The lacteals are merely a portion of the great lymphatic system of the body, which will be described in a future article. See LYMPHATICS. They commence, as has been previously mentioned, in the villi, and possibly also in the intervening mucous membrane; and when an animal is killed while the digestive process is going on, they have, in consequence of their being distended with chyle, the peculiar white or milky appearance which procured for them their name of *vasa lactea*, from their discoverer, Asellius, in 1622. They pass in great numbers, and in a reticulated arrangement, between the layers of the mesentery, the portion of peritoneum (q.v.) which surrounds the gut, and retains it in its proper position. After passing through the mesenteric glands, where their contents seem to become more highly organized, they make their way to the right side of the aorta in the lumbar region, where they finally discharge themselves into an elongated pouch, termed the *receptaculum chyli*. From this pouch, the thoracic duct, containing the chyle, passes upward along the vertebral column till it reaches the level of the arch of the aorta, behind which it runs to the left side, and discharges its contents into the subclavian vein, close to its origin with the internal jugular, its orifice being protected by two valves. The nature of these contents has been already described in the article CHYLE. This chyle is, in reality, incipient blood, which has been formed, as we have already seen, from the food, and has been absorbed from the intestine by the lacteals. We have now traced it to its entrance into the general circulation, and it only remains for it to pass, in conjunction with the venous blood with which it is mixed, through the lungs, in order to be converted into new and perfect arterial blood, fit for the highest processes of organization.

We shall conclude this article with a notice of some of the most striking peculiarities presented by the digestive organs in the lower animals.

In the mammalia, we have three different forms of stomach—the *simple*, the *complex*, and the *compound*. In the *simple* form, the organ consists of a single cavity, as in man, but the form may vary to a great extent. It is most simple and relatively smallest in carnivorous animals. This is the most common form of mammalian stomach. In the *complex* stomach, that viscus is made up of two or more compartments communicating with one another, but often without presenting any marked difference of structure. The kangaroo, the porcupine, and the squirrel, afford good examples of this form of stomach. In the cetacea, the stomach consists of from five to seven cavities, that communicate with each other; but whether their functions are similar or different is not known. The *compound* stomach occurs in the ruminants (the cow, sheep, camel, etc.);

it consists of four distinct cavities, differing very materially in their size, and in the arrangement and structure of the lining mucous membrane. The first, and by far the largest cavity, is the paunch or *rumen*; it occupies a great part of the abdominal cavity, and is the receptacle into which the food is received when first swallowed. The second cavity is termed (from the peculiar arrangement of the lining membrane, which forms deep polygonal cells) the honey-comb or *reticulum*. The third cavity presents a foliated appearance internally, and is hence popularly known as the manyplies. In anatomical works, it is sometimes termed the *psalterium*, and sometimes the *omasum*. The fourth division, termed the reed or *abomasum*, is somewhat of a pyriform shape, and is the true digestive stomach, in which alone gastric juice is secreted, all the preceding cavities being merely for the purpose of preparing the food for the more essential changes which it is here destined to undergo. The food first passes in a crude unmasticated state into the paunch, which, like the crop of birds which we shall presently notice, serves as a receptacle for the food until the act of feeding is concluded, and moistens it with the fluid secreted from its walls. The water, however, which the animal drinks, seems to pass directly into the second stomach. During rumination, small portions of the food pass from the paunch into this second stomach, from whence they are returned, in the form of pellets, to the mouth, where they undergo thorough mastication, and are then returned, as a pulp, by the esophagus directly into the third stomach. The direction of the food into one or other of these cavities is altogether independent of the will, and results from a peculiar arrangement and property of the lower end of the esophagus, which does not terminate at its opening into the paunch on one side, and the second stomach on the other, but is continued onwards as a deep groove or semi-canal, with two lips. If these lips come in contact, they form a perfect canal, leading directly to the third stomach; while if they remain open, the food passes into the first or second stomach. The dry food first swallowed opens the lips and escapes into the paunch, while the masticated food, being soft and pulpy, passes along the groove, without opening its lips, into the third stomach. Here it is diffused over a large surface of mucous membrane, and doubtless undergoes certain changes before entering the fourth or true stomach. In the camel, the dromedary, and the llama, numerous rows of large quadrangular deep water-cells are developed on the parietes of the second stomach, and on the part of the paunch next to that cavity. These cells are surrounded by muscular fibers, which, by their contraction, exclude the food from their interior, and by their gradual opening, the water is allowed to mix in successive small quantities with the food. It is by this arrangement that these animals only require to drink at comparatively long intervals. The intestinal canal of the ruminants is of great length, being sometimes, as in the sheep, more than thirty times the length of the body of the animal; and in herbivorous animals generally, as compared with carnivorous, the canal is very long.

It is in the large intestine that, next to the stomach, we find most varieties of structure. Cuvier has given the following *résumé* of the principal facts connected with this subject, to which, however, there are numerous exceptions: 1. In man, the oranges, and the wombats, there are both cæcum and vermiform appendix. 2. In the other quadrumana, the digitate carnivora, the marsupialia, the rodentia, the pachydermata, the ruminantia, the solipeds, and the amphibious mammals, there is a cæcum (often in vegetable-feeders larger than the stomach, and probably subservient to the digestive process), but no vermiform appendix. 3. In the odontata, the plantigrade carnivora, and the cetacea, there is neither cæcum nor vermiform appendix.

In birds, as in all other classes of animals, the alimentary canal varies according to the nature of the food, being long and capacious, and in some parts highly muscular, in the granivorous tribes, while it is much more simple in those which live on fish and other animal food. We take the common fowl as a good example of the former class. The esophagus, about the middle of its course, and a little above the union of the clavicles (the furculum), presents an enlargement termed the crop or *ingluvies*, which varies in form and structure according to the food, and is provided with numerous glandular follicles. Just before terminating in the gizzard, the esophagus again dilates to form a second but smaller cavity, known as the glandular stomach, *proventriculus*, or *ventriculus succenturiatus*, from whence a copious secretion of gastric juice is poured out and mixed with the food, which, having previously been macerated by the secretion of the crop, now passes on to the gizzard, which is a muscular organ of immense strength, which grinds and crushes whatever is placed in its central cavity—a process that is facilitated by the presence of hard pebbles, which are instinctively swallowed by the bird, and act the part of millstones. There is no very marked division in birds between the large and small intestine, the theoretical limit being indicated by the presence of two (sometimes only one) cæcal appendages.

There are no special points that we need notice regarding the digestive organs of reptiles, except that as the ophidians (serpents) and saurians (lizards) are mostly carnivorous, and most of the chelonians (tortoises) are herbivorous, the apparatus in question is more simple in the former than in the latter.

The amphibia afford us an excellent illustration of the close connection between the nature of the food and the development of the intestinal canal. In the young tadpole of the common frog, which lives upon the soft vegetable matter of our fresh-water ponds and ditches, the stomach is narrow and elongated, and the intestine is of extra-

ordinary length, and of nearly equal diameter throughout, being coiled up in a spiral manner, and distending the capacious abdomen. As the tadpole becomes metamorphosed into a frog, it changes its vegetable food for slugs, worms, grubs, flies, etc., and, at the same time, the alimentary canal becomes very much shortened, and its divisions into stomach, etc., more distinctly marked.

In osseous fishes, the alimentary canal is generally shorter and more simple than in the higher vertebrata, in many—as, for example, the herring—being shorter than the body, and, excepting the stomach, running in nearly a straight line through it. In the cartilaginous fishes, as the sharks, rays, etc., a spiral valve winds in close turns from the pyloric to the anal extremity, leaving merely a small central aperture, along which the contents slowly progress. By this singular arrangement, the intestine, although short in proportion to the length of the animal, presents an enormous absorbing surface.

The limits within which we must confine this article preclude us from noticing the various modifications which the digestive organs present in the various departments of the invertebrate animals; and we shall conclude with a few remarks upon the mode in which digestion is carried on in some of the lowest and simplest animals. The *hydra* or fresh-water polype is a minute animal, consisting of nothing but a bag or stomach, with tentacles surrounding its single orifice. The animalcules, etc., which the hydra catches by these lasso-like tentacles (see *HYDRA*), are drawn into the interior, where they are digested, and applied to the nutrition of the organism, the insoluble portions being rejected by the aperture through which they entered. In the *actinophrys sol*, or sun-animalcule, there is no persistent aperture; but when its radiating filaments—from which it derives its name—have secured a particle of organized matter fit for its nourishment, they twist over it, compress it against the globular body, which first yields, and becomes concave at the point, and finally closes over it, the prey being distinctly visible in the interior. This astomatous animalcule can thus form a mouth and stomach when it requires them. The indigestible remains are ejected by a corresponding reverse process. The *amœba* or *sponge-protens* neither has a mouth and stomach, nor can it construct these organs; it simply folds itself around the solid particles from which it derives its nourishment, and imbibes their nutritious fluids through its cell-wall. We might adduce various other examples of animals devoid of a stomach, but we have brought forward sufficient evidence to show that the old doctrine, that this organ is a necessary constituent of an animal, cannot be sustained, when we approach that debatable-land which separates the two great organized kingdoms of nature.

**DIGGES**, an English family of note in the 16th and 17th centuries. **LEONARD**, b. 1574, wrote *Tectonicum*, briefly showing the exact measuring and speedy reckoning of all manner of lands, squares, timbers, stones, steeples, etc.; *Pantometria*, a practical geometrical treatise; and *Prognostication Everlasting of Right Good Effect, or Choice Rules to Judge the Weather by the Sun, Moon, and Stars*. **THOMAS**, son of Leonard, was an Oxford graduate, and a soldier. He wrote on mathematics and astronomy. **SIR DUDLEY**, son of Thomas, was the author of *Rights and Privileges of the Subject*, and the *Complex Ambassadors*. His son **DUDLEY**, d. 1642, was the author of *Unlawfulness of Subjects taking up Arms against their Sovereign*.

**DIGGING**. The operation of digging is performed with a spade or pronged fork. The spade or fork is thrust in with the foot, and the mass of earth is first loosened by the lever-power of the handle, then lifted and inverted. When this operation is performed in spring or summer, the ground should be dry, so as to obtain pulverization as easily and to as great extent as possible. In stronger soils, which are dug in autumn, a little moisture is desirable, as the land lies fallow, and the frosts of winter afterwards pulverize and reduce it to a proper degree for receiving the crops in spring. Digging is almost entirely confined to the cultivation of gardens, for though a most efficient means of cultivating the soil, it is too expensive for field-crops. It is almost always resorted to, however, in this country for digging over or trenching land which has been in timber, or full of stones or boulders. Until recently, the spade was the only implement used for digging in gardens, but steel forks are coming rapidly into use, being lighter and more easily driven into the soil. Besides preparing the land for plants, the spade and the fork, chiefly the latter, are used for taking crops, such as potatoes and carrots, out of the ground.

**DIGIT** (Lat. *digitus*, the finger), a term applied to the ten symbols of number, 0, 1, 2, etc., to 9; thus, 305 is said to be a number of three digits. Numbers were originally indicated by the fingers, and hence the name. Astronomers use digit to signify a twelfth part of the diameter of the sun or moon, and speaks of an eclipse of seven digits, meaning that seven twelfths of the diameter is covered.

**DIGITAL LINE** is an active principle present in *digitalis purpurea*, or foxglove.

**DIGITALIS**, a genus of plants of the natural order *scrophulariaceæ*, natives chiefly of the s. of Europe and temperate parts of Asia. One only, the common **FOXGLOVE** (*D. purpurea*), is a native of Britain, and is very abundant in some parts of the country, its large purple flowers often giving a gay appearance to dry banks and steep hills. It is not unfrequently admitted into flower-gardens, particularly a white-flowered variety.

Its English name, and the botanical name *D.* (Lat. *digitale*, the finger of a glove), both refer to the form of its flowers. The central and southern parts of Europe produce several species with yellow flowers, one of which, *D. grandiflora*, is not an uncommon ornament of gardens. *D. purpurea* is much valued in medicine. It was first brought into repute by Dr. Withering. Its leaves and seeds are the parts used, generally the former. They are narcotic and poisonous. The leaves have a disagreeable smell when fresh, and a bitter nauseous taste, and are violently emetic and cathartic; but when dried and administered in small and repeated doses, they are diuretic, and therefore sometimes useful in dropsy; and are still more valuable on account of their sedative power over the action of the heart and the circulation of the blood, and are used in diseases of the heart, aneurisms, hemorrhages, etc. They appear also to possess some peculiar power over the brain and nervous system, and have been employed in insanity, epilepsy, and other diseases. They are administered generally in the form either of tincture or infusion. They ought to be collected before the flowers expand. They owe their active properties to a peculiar crystalline principle called *digitoline* (q.v.). The use of *D.* as a medicine requires great caution on account of a property which it possesses—very remarkable in a vegetable medicine—of cumulative action on the system. Many if not all of the species of *D.* appear to possess similar properties with *D. purpurea*, and to be capable of being substituted for it.

**DIGITA'RIA.** See MILLET.

**DIGITIGRADA** (Lat. finger-walking), in the zoological system of Cuvier, one of the tribes of the *carnivora* (q.v.), distinguished by walking on the toes alone, the heel not touching the ground. Among the digitigrade quadrupeds are included the most carnivorous of the *carnivora*, the feline and canine families, hyenas, civets, weasels, etc. The weasel family (*mustelide*), however, forms a connecting link, in respect to the character derived from the mode of walking, between the tribe *D.* and the tribe *plantigrada* (q.v.), being, in fact, semi-plantigrade, and not walking on the mere tips of the toes, like the other digitigrada.

**DIGNE** (Lat. *Dinia*), a t. in the department of the Basses-Alpes, on the Bléonne, 60 m. n.e. of Marseilles, occupies a picturesque situation upon a mountain slope, and is encircled by walls, but its streets are narrow, crooked, and steep, and the houses mean and squalid. Its chief building is the préfecture, once the bishop's palace, a very ordinary edifice. The principal manufactures of *D.* are articles of leather, and it has a trade in dried fruits, honey, wax, woolen and linen cloth, kid-skins, etc. In the neighborhood there are several hot saline springs, temperature 104° F. Pop. '76, 5,540. Of *Dinia*, which is mentioned by Pliny, nothing remains. It is known that it embraced Christianity at an early period, and has given title to a bishop since the year 340. In the year 1629, a plague reduced the population of *D.* from 10,000 to 1500.

**DIGNITARY**, in canon law, originally signified an ecclesiastic of superior rank than a priest, such as bishop, dean, etc.; it now includes also canons and prebendaries.

**DI HONG**, or **SANPO'**, the largest feeder of the Brahmaputra, rises on the n. side of the Himalayas, near the sources of the Sutlej and the Indus, in lat. 30° 25' n., and long. 82° 5' e., and bursts through that great mountain-chain near lat. 28° 15' n., and long. 95° 10' e., having pursued through Thibet an easterly course of about 1000 miles. Finally, it joins the more easterly branch of the Brahmaputra, near the n.e. angle of Assam.

**DIJON**, a t. of France, in the department of Côte d'Or, formerly capital of the old duchy of Burgundy, in lat. 47° 20' n., and long. 5° 2' e., and about 195 m. s.e. of Paris by railway. *D.* occupies a most delightful situation in a fertile plain on the right bank of the Ouche, and at the base of the vine-clad hills which produce the famous Burgundy wines. The environs are exceedingly beautiful. *D.* is surrounded by old walls, originally having but five gates, and the ramparts being tastefully planted with fine trees, furnish very agreeable promenades. The town is for the most part well and regularly built, and the streets spacious and clean. Among the public buildings, which are numerous and imposing, the chief are the cathedral, a massive Gothic structure, dating from the 13th c., with a tall wooden spire, above 300 ft. high; the church of Notre Dame, a noble specimen of the purest Gothic architecture; the church of St. Michael, with a splendid renaissance front; the theater, a handsome building, with a fine Corinthian portico; and the palace of the dukes of Burgundy, now used as the town-hall, and much modernized externally, but possessing interiorly some of its earlier features, and containing a museum very rich in monuments of the middle ages, besides a library of 50,000 volumes, and several hundreds of manuscripts. *D.* is also the seat of a university academy with three faculties—law, science, and letters—and possesses, in addition, a royal college, a theological seminary, a botanic garden, and an academy of art. The manufactures of *D.* consist of woolen cloth, blankets, hosiery, leather, vinegar, chemical products, etc.; and there are salt refineries, distilleries, and breweries; but the town is mainly dependent on its trade in the wines of Burgundy. Pop. '76, 45,607. *D.* dates from Roman times, its ancient name being *Dibio*. It came into the possession of the Burgundians in the 5th c., and from them passed to the Franks. In the 9th c., it was ruled by counts of its own, under the suzerainty of the bishops of Langres. In the 11th c., it was united to the duchy of Burgundy, of which it became the capital, and the usual

residence of the dukes, who rebuilt and greatly enlarged and improved it. In Oct., 1870, after a sharp engagement before the city, D. capitulated to a German force. There was again severe fighting here in Jan., 1871.

**DIKAMALI**, a gum-resin which exudes, in amber-colored transparent drops, from the ends of young shoots of *gardenia* (q.v.) *lucida*, an Indian tree. It has a very powerful fragrance, and has been found extremely useful in hospitals, in keeping away flies, and especially as a dressing for wounds and running sores.

**DIKE**. See **DYKE**, *ante*.

**DIKE**, in geology. See **DYKE**, *ante*.

**DIKOWA**, or **DEGOA**, a large t. of Bornu, Central Africa, about 80 m. s.w. of lake Tchad. It is in a great cotton growing district, and is a place of considerable trade. The spinning and weaving of cotton are also extensively carried on. The houses are mostly of clay, but each has its court-yard. Pop. supposed about 30,000.

**DILAPIDATION**, in English law, is where an incumbent suffers his parsonage-house or outhouses to fall down, or be in decay, for want of necessary reparation; or pulls down or destroys any of the outhouses or buildings belonging to his living; or destroys woods, trees, etc.; for it is said to extend to committing or suffering any willful waste on the inheritance of the church.—*Stephens' Eccl. Law*. D. is a species of the legal injury known as waste (q.v.). A rector or vicar is bound to keep his residence and the chance of the church in repair, but not to supply or maintain anything in the way of ornament, as painting, white-washing, or papering. An ecclesiastical person suffering the church-property to get out of repair, is subject to an action for D. at the instance of his successor (13 Eliz. c. 10, s. 2); and by 14 Eliz. c. 11, s. 18, the money so recovered must be applied to the repairs. By 5 and 6 Vict. c. 108, s. 19, being an act to empower ecclesiastical corporations to grant long leases, it is provided that the incumbent shall not be liable for D. occurring during such leases.

**DILATORY PLEAS**. See **PLEA**.

**DILEMMA**. A true D. is defined by Whately as "a conditional syllogism with two or more antecedents in the major, and a disjunctive minor." The following D., of the kind called destructive, will perhaps convey a clearer notion than any definition: "If this man were wise, he would not speak irreverently of Scripture in jest; and if he were good, he would not do so in earnest; but he does it, either in jest or earnest; therefore, he is either not wise or not good." There being two conclusions, one or other of which your opponent must admit, he is in a manner caught between them; hence we speak of the *horns* of a dilemma.

**DILETTANTE** (pl. *dilettanti*, Ital.), in its original sense, is synonymous with an *amateur*, or lover of the fine arts. It is often used as a term of reproach, to signify an amateur whose taste lies in the direction of what is trivial and vulgar, or of a critic or connoisseur whose knowledge is mere affectation and pretense. It is sometimes assumed, in a spirit of self-depreciation, by those who are unwilling that their critical acquirements or artistic productions should be judged by the rules which would be applied to those of persons who had made a professional study of art. It was in this sense that it was assumed by the Dilettanti Society (q.v.).

**DILETTANTI SOCIETY**, a body of noblemen and gentlemen by whose exertions the study of antique art in England has been largely promoted. The society was founded in 1734, and held its meetings at the Thatched House tavern in St. James' street. It was in its beginnings simply an amateur club, its object being to combine social and friendly intercourse with the cultivation of artistic knowledge and the gratification of artistic tastes. But its funds having accumulated to a large amount, its members resolved, in 1764, to fit out an expedition for the purpose of collecting details and drawings of the most remarkable artistic monuments of antiquity. The persons selected for carrying out this important undertaking were Mr. Chandler, of Magdalen college, Oxford, the editor of the *Marmora Oxoniensis*; Mr. Revett and Mr. Stewart, the authors of the magnificent work on Athenian antiquities; and Mr. Pars, a talented young artist. Having spent two years in Greece, they returned in 1766, bringing with them the materials for the two splendid volumes on the antiquities of Ionia, which were published at the expense of the society. Architecture had been the first object of their inquiries, but their attention was now turned to sculpture, which was then at the lowest ebb in England. A series of the finest antique statues, bas-reliefs, and busts were selected and engraved with the greatest care. This work appeared in 1809, with dissertations by Payne Knight. In 1811, a second architectural exploring-party was dispatched by the society to Asia Minor, consisting of Mr. (afterwards sir William) Gell, Mr. Bedford, and Mr. Gandy. Two volumes were issued, one in 1817 entitled *The Unedited Antiquities of Attica*, and a second on *Antique Sculpture* in 1835. For these spirited exertions in their behalf, the public have been indebted to a club of some sixty private gentlemen.

**DILIGENCE**, in the law of Scotland, is a term used in various significations. 1. It means the care incumbent on the parties to a contract with regard to the preservation of the subject matter. 2. The warrants issued by courts for enforcing the attendance of witnesses and the production of writings. 3. The process of law by which person,

lands, or effects are attached either on execution (q.v.) or in security for debt. In the second of these senses, it corresponds to the English *subpœna*; and in the third, generally to execution. The first can scarcely be regarded as a technical meaning.

**DILIGENCE**, the name given in France to a public conveyance of the nature of a stage-coach. It is a huge, strong-built vehicle, with four broad wheels, weighing about 5 tons, and is drawn by 4 stout horses, at the rate of about 6 miles an hour. It consists of 3 chief compartments: the front, called the *coupe*, for 3 persons; the second, called the *intérieur*, for 6 persons; and, lastly, the *rotonde*, entered from behind, for 6 persons. Aloft in front, is the *banquette*, where the *conducteur* is seated; and behind this, underneath a thick leather covering, passengers are sometimes huddled among luggage and goods, with little regard to their comfort. All the places in the body of the vehicle are numbered, and assigned in the order of booking. Usually an effort is made to be booked early, in order to secure corner-places. In booking, it is customary to pay only a portion of the fare, called *arrhes*; the remainder being paid at the end of the journey. For the *arrhes*, a receipt or bulletin ought to be given. Without this security, a traveler may be put down half-way and cheated out of his fare, or he may be compelled to pay over again. The driver being concerned only with the horses, the entire management of the vehicle, including the charge of the drag or break, devolves on the *conducteur*, a trustworthy but most dictatorial personage, dressed in a blue cloth jacket and cap, and having a badge on his breast indicative of his dignity. The greater number of the diligences in France belong to two companies in Paris—the *Messageries Impériales* and the *Messageries Générales*. The system of diligences, however, has been latterly much broken up by railway transit.

**DILKE**, Sir CHARLES WENTWORTH, 1810-69; a native of London, educated at Cambridge. He assisted his father, the editor of the *Athenæum*, in literary work, and gave much attention to the learned societies. He was a zealous promoter of the great exhibition of 1851, at the close of which the queen offered him knighthood, which he declined. He was one of the English commissioners to the New York exhibition of 1853, and prepared the report upon it. He was also one of the five royal commissioners for the exhibition of 1862. In 1865, he was a member of parliament, and in 1869, representative of England at the St. Petersburg horticultural exhibition. He was knighted by the queen soon after the death of the prince consort.

**DILKE**, Sir CHARLES WENTWORTH, b. 1843; son of sir Charles Wentworth; an English politician, author, and lawyer; educated at Cambridge. He has traveled extensively in the United States, Canada, and the British countries in the east, and embodied his observations in *Great Britain; a Record of Travel in English-speaking Countries during 1866-67*. In 1868, he was chosen a member of parliament. After his father's death, he became the editor of the *Athenæum*, and succeeded to the title. In politics he is a strong republican leader.

**DILL**, *Anethum*, a genus of plants of the natural order *umbellifera*, having compound umbels without general or partial involucre, the border of the calyx minute but 5-toothed, yellow involute petals, and dorsally compressed lenticular fruit. The Common D. (*A. graveolens*) is an annual or biennial plant, which grows wild in corn-fields in the east and in the countries around the Mediterranean, but is quite hardy in Britain. It has from a very early period been in general cultivation as an aromatic, stimulant, and carminative. It has a stem 1 to 4 ft. high, bearing at top a flat umbel of 10 to 30 rays; the leaves much divided, and the final segments thread-like. It has a strong peculiar aromatic smell and taste; the leaves are sometimes used for flavoring pickles, sauces, etc. The fruit (*dill seed*) is used in medicine, chiefly for relief of flatulence and griping in infants, and is administered in the form of *dill water*, in the preparation of which *oil of dill* is employed; a pale-yellow essential oil, on which the properties of the plant depend, and which is obtained by distillation.—SOWA D. (*A. sowa*) is a native of Bengal, and is much cultivated in the East Indies for its fruit, which is variously used in medicine and flavoring. It is a common ingredient in curries. The plant much resembles common D., but its flavor is stronger.

**DILLEN**, or **DILLENIIUS**, JOHANN JAKOB, 1687-1747; a German botanist, educated at Giessen. He went to England in 1721, and was a co-laborer with William Sherard, the most eminent English botanist of the time. In 1728, he was appointed professor of botany at Oxford. He wrote many works upon his favorite themes, some of which received high praise from Linneus.

**DILLENIACEÆ**, a natural order of exogenous plants, consisting chiefly of trees, shrubs, or half-shrubby plants, natives of tropical and subtropical regions, allied to the natural order *ranunculaceæ* (q.v.), but very different in general habit, and also to *mag-noliaceæ*, which in habit they more resemble. They have usually alternate leathery leaves, without stipules. The flowers are sometimes solitary, sometimes in racemes or panicles; the calyx of 5 persistent sepals; the corolla of 5 deciduous petals. The stamens are numerous. The fruit consists of 2 to 5 distinct or coherent, dry or succulent, carpels. The seeds have an aril. Astringency is a general property of the order; and a number of species are used as vulneraries and for other medicinal purposes in their native countries. Some species of *dillenia* are large trees, and afford excellent timber.

The young calyces of *D. scabrella* and *D. speciosa* have a pleasant acid taste, and are used in curries, and the fruit of *D. speciosa*, although very acid, is eaten with sugar; the juice, mixed with water, is employed in India as a cooling beverage in fevers. The fruit of *D. elliptica* is used to make a sauce for fish in Amboyna. Many of the plants of this order are remarkable for the magnificence both of their foliage and their flowers. It contains about 200 known species.

**DILLINGEN**, a t. in Bavaria on the Danube, 24 m. n.w. of Augsburg; pop. '75, 5,029. Its principal buildings are the royal palace, the royal gymnasium and Latin school, two Episcopal seminaries, a Capuchin monastery, a Franciscan nunnery, a deaf and dumb asylum, and some fine churches. The principal occupations are ship-building, the shipping trade, and the manufacture of paper, cloth, and cutlery. The place was taken by the Swedes in 1632 and 1648, by the Austrians in 1702, and by the French in 1800.

**DILLMANN, CHRISTIAN FRIEDRICH AUGUST**; b. 1823; a native of Würtemberg, educated at Tübingen. In 1854, he was appointed professor of oriental languages at Kiel, and in 1864, he accepted a call as professor of theology at Gießen. In 1869, he succeeded Hougstenberg in the university of Berlin, as professor of Old Testament exegesis. He is noted chiefly for researches in the Ethiopic language, of which he has published a grammar, dictionary, and other works.

**DILMAN**, a t. of northern Persia, in the province of Azerbijan, 50 m. n.n.w. of Urumiyah, and 10 m. w. of the northern extremity of the lake of that name. It is of considerable extent, has clean streets, and is surrounded by gardens and orchards. D. is a new town; the former town of the same name, distant about 4 m., is now in ruins. It is described by St. Martin as a very ancient Armenian city, and the large plain in which it was situated is still inhabited by Armenians, Catholics, Nestorians, etc. Pop. of D. estimated at 15,000.

**DILUENTS** (Lat. *diluo*, I dilute), medicines whose purpose is to dilute the blood, and increase the quantity of the excretions generally. The simplest and best of diluents is water; but all watery fluids, such as lemonade, soda-water, beer, infusions or ptisans, tea, etc., may be regarded as coming under this designation. See DEMULCENTS.

**DILUVIUM**, a term formerly given by geologists to those strata which they believed to have been formed by the deluge, and more particularly to the bowlder clay. The altered opinions as to the origin of these beds have caused the word to fall into disuse. When the adjective—diluvial—is employed by modern writers, it is to characterize those accumulations of gravel or angular stones which have been produced by sudden or extraordinary currents of water.

**DI MA**, a large t. of Abyssinia, in the state of Amhara, on an affluent of the Abai, 150 m. s.s.e. of Gondar. The houses are mostly of stone, and the church is one of the largest edifices in Abyssinia. The town is divided into many quarters by stone walls.

**DI'MAN, JEREMIAH LEWIS, D.D.**, b. R. I., 1831; a graduate of Brown university and Andover theological seminary. After traveling abroad, he was settled over the First church (Congregational), Fall River, and in 1856, over the Harvard church in Brookline, Mass. He was appointed to the chair of history and political economy in Brown university in 1864.

**DIME**, the tenth part of a U. S. dollar (see DOLLAR), and equal to about fivepence English.

**DIMENSION**. In geometry, a line, whether straight or curved, has only one dimension, or measurement—namely, length; a surface has two—length and breadth; and a solid has three dimensions—length, breadth, and thickness, or depth. These three measurements or dimensions determine all forms of extension.—In algebra, the term dimension is applied in much the same sense as *degree*, to express the number of literal factors that enter into a term. Thus,  $x^2$ ,  $xy$ ,  $2ab$ , are all of two dimensions, or of the second degree;  $x^3$ ,  $x^2y$ ,  $abc$ ,  $\frac{a^2bc}{d}$ , are of three dimensions, etc.

**DIMIDIA'TION**, in heraldry, a mode of marshaling arms, adopted chiefly before quartering and impaling according to the modern practice came into use, and subsequently retained to some extent in continental though not in English heraldry. It consists in cutting two coats of arms in half by a vertical line, and uniting the dexter half of the one to the sinister half of the other. Coats of husband and wife were often so marshaled in England in the 13th and 14th centuries. Mr. Planché traces the double-headed eagle of the German empire to a dimidiated coat, with half an eagle for the eastern, and another half for the western empire.

**DIMINUENDO** (Ital. diminishing), a term in music, having reference only to the power of the sound, and in no way affecting the *tempo*, as many think. D. can be applied to a single note, when it is a long note, as well as to a passage of many notes. D. is so nearly of the same meaning as decrescendo, that it is frequently marked with the same sign, thus 

**DIMINUTIONS.** a word sometimes used in heraldry for differences, marks of cadency, and brisures, indifferently.

**DIMINUTIVES** are forms of words, chiefly of substantives, in which the primitive notion has become lessened or diminished, as *hillock* = a little hill. With littleness is associated the idea of neatness, and also of needing protection; hence D. are used as terms of endearment; sometimes they imply contempt. There is perhaps no language without D.; and the most common method of formation is by the addition of a syllable. This, however, is not the only method; *tip* from *top*, by attenuating the vowel, and *kid* from *goat*, are as genuine D. as *hillock*. The commonest of the English diminutive affixes are *ock*, *kin*, *el* or *le*, which are of Gothic origin, and *et* or *let*, of classical origin; as in *bullock*, *lambskin*, *kernel* (little corn), *laneet*. According to Dr. Latham, the termination *ling*, or rather *ing*, was originally patronymic: "Ida was the son of Eoppa," was expressed in Anglo-Saxon by *Ida was Eopping*. From the notion of the filial relation, the transition is easy to that of littleness and endearment, as in *darling*, *duckling*. Contempt predominates in *shaveling* (a monk) and others.

D. often occur in proper names; *Perkin* is the diminutive of *Peter*, *Jenkin* of *John*. These have settled down into permanent and distinct names; but in the language of fondness and familiarity, *Charles* becomes *Charley*, *John*, *Johnny*, etc. In Lowland Scotch, this form of diminutive is not confined to proper names, but is applied to every object, animate or inanimate—*laddie*, *horsie*, *wifie*, *firie*. Sometimes one diminutive affix is joined to another, as *lussock*, *lussockie*; and in expressions like *a wee, wee bit horsikie*, the diminution is carried to the fifth degree. It is principally in the mouths of the people and in friendly familiarity that these diminutive forms are most common; and some languages and dialects are rich in them beyond others. Italian is remarkable in this respect, especially the Tuscan dialect; *casa*, house, becomes *casarella*, little house, and *casarellina*, pretty little house; from *fratello*, brother, which is itself a diminutive of the Lat. *frater*, children, it is said, may be heard forming such fond names as *fratellinucciettinetto*. The affectionateness and bonhomie of the Germans expresses itself largely in this form; *vater*, father, becomes *väterchen*, dear father; and even the pronoun *du*, thou, is made into *düchen*, and *duli*.

D. are not confined to nouns: *whitish* is the diminutive of the adjective *white*; and *tipple*, *scribble*, *dandle* are examples of diminutive verbs. Opposed to D. are AUGMENTATIVES, which abound in the Romanic languages, especially in Italian, and express not only largeness, but coarseness and vulgarity; *casotta* is a large house; *carallaccio*, a worthless horse. Our word *balloon*, which is of foreign origin, is of this form, and means a large ball. Such words as *drunkard*, *bruggart*, *buzzard*, seem to be genuine English augmentatives.

**DIMITY**, a stout figured cotton-fabric, used chiefly for bed-hangings. The figure or stripe is raised on one side, and depressed on the other, so that the two faces present reversed patterns. D. is commonly white, or of a single color; but variegated dimities are now made, the pattern and the ground being of different colors.

**DIMORPHOUS** (Gr. *dis*, twice; *morphe*, shape or form) is the term applied to a substance when it exhibits the property of crystallizing in two distinct forms or systems. See CRYSTALLOGRAPHY. Thus, sulphur, as found crystallized naturally, and as obtained by the spontaneous evaporation of its solution in bisulphuret of carbon, or in chloride of sulphur, presents itself in crystals of the form of octohedra, with a rhombic base, and thus belongs to the *prismatic system*; but when sulphur is heated to fusion, and then slowly cooled, prismatic crystals of an amber color are obtained, which belong to the *oblique system*. The latter form of sulphur is not permanent, and the crystals gradually become opaque, and pass into the form of numberless octohedra. In their turn, the octohedral crystals, when kept at a temperature of 230° F. for some time, pass into the prismatic form. Carbon is another illustration of *dimorphism*. Thus, carbon crystallizes in the diamond in the regular system as the octohedron and allied forms; while in the condition of graphite or black lead (q.v.), as obtained by the cooling of its solution in fused cast-iron, it is in the form of hexagonal crystals belonging to the rhombohedral system. Carbonate of lime and iodide of mercury are also good examples of dimorphism; and some substances, such as the sulphate of nickel, sulphate of zinc, seleniate of nickel, and the seleniate of zinc, crystallize in three different systems, and are thus *trimorphous*.

**DI'NABURG**, a fortified t. and important military station in Russia on the Dwina, reached by the St. Petersburg and Warsaw railroad, 120 m. s.e. of Riga; pop. '69, 29,613. It has many manufactories, and a flourishing trade.

**DINAGEPORE**, the district of the below mentioned city, stretches in n. lat. from 24° 53' to 26° 33', and in e. long. from 88° 2' to 89° 16', containing 4,126 sq.m., and '71, 1,501,924 inhabitants. The country is flat, its only eminences being mere undulations; and, from the proximity of the Himalayas, the whole tract is little but a net-work of water-courses, many of the channels, however, becoming periodically dry. The winds are more variable than is usual elsewhere in India, and hail-stones are occasionally of such weight as to kill men and cattle. Rice is the principal crop, and fish are singularly plentiful.

**DINAGEPORE**, a city of the province of Bengal, with '71, 13,042 inhabitants, stands 261 m. to the n. of Calcutta, in lat. 25° 34' n., and long. 88° 38' east. It is watered by an offset of the Attre, called the Purnabada, which, through the Mahanunda, enters the Lower Ganges from the left. The place is devoid of architectural pretensions.

**DINAN**, a very old t. of France, in the department of Côtes-du-Nord, on the Rance, 30 m. n.w. of Rennes, and 14 s. of St. Malo. The situation of D., on the summit of a steep hill of granite, and with the Rance flowing through a valley 250 ft. below, is romantic in a high degree. It is surrounded by old walls, pierced by four gates, and was formerly defended by a strong castle, part of which has been converted into a prison. In the older district, the streets are crooked, narrow, and steep, many of the buildings being crazy constructions of wood; but in some parts, its overhanging houses, and arcades resting on carved granite pillars, present many picturesque architectural features, attractive to the antiquary and the artist. The cathedral of St. Sauveur is a beautiful ornate edifice, built in the Romanesque style, containing the heart of the famous French warrior Bertrand du Guesclin. D. has manufactures of fine linen and of sail-cloth, of cotton and woolen goods, beet-root-sugar, etc. It has also some barge-building yards, and, owing to its position near the mouth of the Rance, has a good coasting and inland trade. Pop. '76, 7,978. A few miles off lies the village of Corseult, built on the ruins of the capital of the ancient Curiosolita. In the fields round about the village are still occasionally found ancient utensils, Roman coins, and traces of a temple dedicated to Mars.

**DINANT**, a t. of Belgium, in the province of Namur, 14 m. s. of the city of that name. It is situated on the Meuse, in the midst of extremely picturesque scenery. The most noteworthy buildings of D. are the church of Notre Dame, an ancient and richly decorated Gothic structure, and the town-house, once the palace of the princes of Liège. D. has several salt-refineries, mills for sawing marble, some quarries of which are worked in the vicinity, paper-mills, breweries, and tanneries. It has also manufactures of woolen stuffs, paper, hats, cards, and cutlery. The gingerbread of D., composed of rye-flour and honey, is famous, and has an extensive sale. Pop. '70, 1,600. D., which dates from the 6th c., has suffered greatly from frequent sieges. In 1466, Philip, duke of Burgundy, attacked it with a strong force, and, when the town was taken, in retaliation for the hanging of the messengers whom he had sent to summon the town to surrender, he ordered 800 of the inhabitants to be tied in couples, back to back, and cast into the Meuse. At this time, also, the town was burned, and the walls leveled.

**DINAPORE**, an important military station in the Indian province of Behar, stands on the right bank of the Ganges, 10 m. above Patna, in lat. 25° 37' n., and long. 85° 7' east. The barracks are spacious and elegant; and the pop.—exclusive of a garrison of between 14,000 and 15,000—numbers (1871) 27,914. In the mutiny of 1857, D. acquired an unenviable notoriety. On 25th July, nearly eleven weeks after the commencement of the outbreak, the native troops, consisting of three regiments, rose against their officers, and that in the presence of a European force, which, if well handled, was as able, as it was ready, to crush them. After escaping with comparatively little loss, the insurgents clinging instinctively together, carried on a desultory warfare on their own account with various success. See ABRAH.

**DINARCHUS**, the orator, son of Sostratus, b. Corinth, 361 B.C. At 25 he was a writer of speeches for the law courts. He had been a pupil of Theophrastus, and early gained oratorical repute. In 324 B.C., he wrote three or more of the speeches in the case of the prosecution of nine men for taking bribes from Harpalus, the fugitive treasurer of Alexander. The speeches were "Against Demosthenes," "Against Aristogiton," and "Against Philocles."

**DINARIC ALPS**, that branch of the Alpine system which connects the Julian Alps with the western ranges of the Balcan. It extends in a south-easterly direction, from Mt. Klek, e. of Fiume, to the mouth of the Narenta; and stretching along the borders of the Adriatic, it spreads its ramifications through the greater part of Croatia, Dalmatia, and Herzegovina. The D. A., the highest summits of which are Mt. Dinara and Mt. Prolok, seldom exceed 7,000 ft. in height. The range is principally calcareous.

**DINDIGUL**, a t. of India, in the British district of Madura, presidency of Madras, at the extremity of a valley of the same name, on a feeder of the Cauvery, 247 m. s.w. of Madras city. It is 700 ft. above the level of the sea, and built on a gentle declivity; the streets are wide; the houses well built, and the bazaar plentifully supplied. The pop. is supposed to be between 6,000 and 7,000, exclusive of the military. The fort is situated on a wedge-shaped mass of gneiss, which rises to a height of 250 ft., perfectly naked, except near the summit, where some stunted trees and shrubs grow on patches of thin soil. The ascent is on the eastern side by a flight of stone steps, the other sides being nearly perpendicular. Near the summit, there is a well of great depth, popularly reputed unfathomable, which yields excellent water.

**DINDORF, WILHELM**, b. 1802; a German critic and philologist. He was a zealous student of classical literature, and became professor of literary history. He has published critical editions of Demosthenes, Aristotle, Sophocles, Euripides, and Josephus. His editions are held as high authority.

**DING'ELSTEDT, FRANZ VON**, b. 1814; a German poet, native of Hesse. In 1843, he was librarian to the king at Stuttgart; became superintendent of the royal theater at Munich in 1850, director of the court opera at Vienna in 1867, and director of the city theater there in 1871. His early poems were mainly political. At a late period he wrote *Night and Morning*, and the *House of Barneveldt*, a tragedy. He married Jenny Lutzer, a famous singer.

**DINGLE**, a seaport, the most westerly town in Ireland, is situated in co. Kerry, in a hollow on the n. side of Dingle bay, near the west end of a mountainous peninsula (30 m. by 7), 39 m. w.n.w. of Killarney. It chiefly consists of one street, and has an antique aspect, some of the present houses having been built in the 16th c., in the Spanish style, with stone balconies, etc. Pop. '71, 2,117. The chief exports are corn and butter to Liverpool. D. was incorporated in 1585. In the 17th c., it had much trade with Spain, exchanging tanned hides, Irish friezes, woolen stockings, salt beef, salmon, and butter, for wines and spices. Dingle bay is an indentation of the sea, on the w. of Kerry, between Brae head, Valentia isle, on the s., and Dunmore head and Blasket isles on the n., from which points, which are 18 m. apart, it runs 24 m. e.n.e., narrowing to 7 miles. The harbor is a landlocked creek in the bay, admitting ships of 300 tons up to the town of D., and forming a pretty safe retreat from the prevalent w. winds of Dingle bay.

**DINGO**, *Canis dingo*, the native dog of Australia, regarded by some naturalists as a distinct species, by others as a mere variety of *canis familiaris*. It exists both in a wild and in a domesticated state; but there is no good reason for thinking that the wild race has originated from dogs introduced from some other country by man. The domesticated D. is about the size of a shepherd's dog, the wild one is larger. The wild D. is found in all parts of Australia. It is of a tawny color, has a large head, with muzzle somewhat fuller than the shepherd's dog. The ears are short and erect, the tail bushy, but not so bushy as that of a fox. In running, the D., unlike dogs in general, carries the head high, the ears erect, and turned forward. In a wild state, it does not bark. It is very destructive to the sheep of the colonists, and its delight is to kill as many as possible before proceeding to eat. It is very fierce and courageous, but capable of strong attachments.

**DINGWALL**, a royal and parliamentary burgh, the county town of the united counties of Ross and Cromarty, in the s.e. of Ross-shire, at the head or s.w. end of the Cromarty firth, 11 m. n.w. of Inverness. In Scandinavian, D. means law or court hill; and in Gaelic, it is called Inverpheoran. It consists chiefly of a long street, and lies low, on what was formerly a swamp, amid rich, fertile, and well-wooded ground, at the entrance to the beautiful valley of Strathpeffer, the famous sulphureous springs of which are five miles to the west. A short canal brings vessels drawing 9 ft. of water up to the town, where there is a station of the Highland railway, and also of the Dingwall and Skye railway. Its prosperity depends on agriculture. Pop. '71, 2,125, many speaking Gaelic, though all understand, and usually speak, English. It unites with Tain, Dornoch, Wick, Kirkwall, and Cromarty in sending one member to parliament. Near to D. is a vitrified fort, on a conical hill, and there are traces of an ancient castle, where the earls of Ross held their courts.

**DINICHTHYS** (Gr. meaning "terrible fish"), the largest of the fossil fishes of the Devonian formation. Its body, according to Dr. Newberry, was 15 or 18 ft. long, and 3 ft. thick. The jaws were armed with two strong, sharp front teeth, and were also arranged at their joints in such a manner as to act like a pair of shears. This structure has a strong resemblance to the jaws of the lepidosiren, a living fish, the nearest allied to the reptiles. The head and forepart of the body was covered with large plates.

**DINKELSBUHL**, a t. of Bavaria, situated on the Wernitz, 44 m. s.w. of Nuremberg. It is an ancient walled town, and was formerly a free city of the empire. It has important manufactures of hosiery, coarse linen, straw-hats, paper, etc.; and a dye-work, brewery, and mills. D. suffered much during the thirty years' war. Pop. '71, 5,213.

**DINNER**. See MEALS.

**DINOC'RATES**, a Greek architect of the time of Alexander the great. He applied to the courtiers for an introduction to the Macedonian king, but was put off from time to time with vain promises. Impatient at the delay, he is said to have laid aside his usual dress, bearded his body in oil in the manner of an athlete, thrown a lion's skin over his shoulders, and, with his head adorned with a wreath of palm branches, and a club in his hand, made his way through a dense crowd which surrounded the royal tribunal to the place where the king was dispensing justice. Amazed at the strange sight, Alexander asked him who he was. He replied that he had come into the royal presence to make known a scheme which would be worthy of the consideration of the greatest monarch in the world. Out on Mt. Athos, a mountain rising like a pyramid to a height of 6,780 ft., topped with a cone of white limestone, he proposed to construct the gigantic figure of a man, holding a large city in his right hand, while in his left he held a gigantic tank large enough to contain all the water from the brooks in the peninsula. The story goes that the king was not displeased with the idea, though thinking it impracticable. Alexander, however, was so delighted with the man, and his bold and

daring conceptions, that he carried D. with him on his campaigns against Darius. He was employed by the king to design and lay out the city of Alexandria. The city was founded in 332 B.C., but the untimely death of D. prevented it from assuming the proportions intended by its designer. The Ephesians, whose temple of Diana had just been burnt down, employed him in its reconstruction. But perhaps the most original of all his conceptions was his design for a temple to Arsinoë, wife of Ptolemy II., king of Egypt. The roof of the building was to have been composed of a mass of load-stones, strong enough to hold floating in the air and suspended within the temple an iron statue of the queen.

**DINORNIS** (Gr. *deinos*, terrible or wonderful, and *ornis*, a bird), a genus of large birds of the tribe *brevipennes* (q.v.), of which no species is now known to exist, but of which the bones have been found in New Zealand, in the most recent deposits, in the sand of the sea-shore, in swamps, in the soil of forests, in river-beds, and in caves; and concerning which, along with other large birds nearly allied to them (*palapteryx* and *aptornis*), traditions are still current among the natives, rendering it probable that they continued to inhabit New Zealand, if not to the 18th, at least to the 17th century. The name by which these birds are known in the traditions of New Zealand is *moa*. They are said to have been decked in gaudy plumage, for the sake of which they were objects of pursuit, as well as for their flesh, which was much esteemed. They are also described as having been stupid, fat, and indolent birds, incapable of flying, living in forests and mountain-fastnesses, and feeding on vegetable food. With all this, the inferences deduced from their bones by comparative anatomists perfectly agree. These bones are not properly fossil or mineralized, but retain great part of their animal matter. It is even thought not impossible that some of the smaller species of D. may yet be found alive; of the larger ones, this can no longer be hoped. And these much exceeded in size any existing bird, some of the bones being at least twice the size of those of the ostrich; but the body seems to have been more bulky in proportion, and to have more resembled that of the dodo, although the legs were long, and *D. giganteus* must have stood at least ten feet and a half in height. The frame-work of the leg is the most massive of any in the class of birds, and the bones are remarkable for the solidity of their structure. The toe-bones of *D. elephantopus* almost rival those of the elephant.

The number of bones of D. which have been found is great; several species have been distinguished, and an almost complete restoration of skeleton has been effected. The first bone ever seen by a naturalist—a bone of the leg—was brought under the notice of prof. Owen in 1839; and it is worthy of being borne in mind, that from that one bone he assigned to the D. its true place in the system of nature, and pointed out some of the most important characters which are now most fully proved to have belonged to it.

**DINOSAURIA** (Gr. terrible or wonderful lizards), an order of extinct lizards, which are found in the lias, oolite, and wealden, and disappear in the lower cretaceous beds. They were gigantic reptiles, with a structure approaching nearer to the mammalian type than any other of their class. Their bodies were supported, at a considerable height, on four strong limbs, and the sacrum was composed of five amalgamated vertebrae. The principal genera are *megalosaurus* (q.v.), *iguanodon* (q.v.), and *hylæosaurus* (q.v.).

**DINOTHERIUM** (Gr. terrible or wonderful beast), a remarkable extinct animal, the cranial bones of which are found in the miocene formations of Germany, France, etc. The animal was provided, like the elephant and the walrus, with a pair of long tusks; but these projected from the end of the lower jaw, which is deflected downwards, at a right angle to the body of the jaw. In addition to the two tusks, there were five double-ridged grinders on each side of both jaws. The nasal cavity is large, apparently supplying attachment for a trunk, as in the elephant. No body or limb bones have yet been found so associated with those of the skull, as to show that they belonged to the same animal. Hence the true position of the D. has not been satisfactorily determined. Cuvier and Kaup have referred it to the neighborhood of the tapir, supposing it to have been an inhabitant of large lakes. De Blainville, on the other hand, makes it a herbivorous cetacean, like the manatee.

**DINWIDDIE**, a co. in s.e. Virginia, between the Appomattox and Nottaway rivers, crossed by the Atlantic, Mississippi, and Ohio, and the Petersburg and Weldon railroads; 540 sq. m.; pop. '70, 30,702—17,664 colored. It has a rolling surface and good soil, producing tobacco, corn, etc. Co. seat, Dinwiddie Court-house.

**DINWIDDIE, ROBERT**, 1690–1770; native of Scotland; lieutenant-governor of the Virginia colony, 1752–58; in the latter year he returned to England. He appointed Washington adjutant-gen. of one of the military districts of the colony; and also commissioned him to remonstrate with the French gen. on the Ohio, for invading British possessions. Dinwiddie's arrogance and peculiar ideas concerning his own importance made him very unpopular. When he left the country he was suspected of having appropriated for his own use \$100,000 of the public money.

**DIOCESAN** is a bishop viewed in relation to his own clergy or flock.

**DIOCESAN COURTS.** See CONSISTORY and COMMISSARY.

**DIOCESE** (Fr., from Gr. *dioikesis*, administration; and *dioikeo*, to govern), the territory over which a bishop exercises ecclesiastical jurisdiction. The term occurs as early as the time of Cicero, as the special designation of districts in Asia Minor. In the organization of the Roman empire introduced by Constantine the great, the designation diocese was applied to the larger divisions, which were subdivided into provinces. About the middle of the 5th c., the dioceses of the empire were the East, Egypt, Asia, Pontus, Thrace, Macedonia, Dacia, Illyria, Italy, Africa, Gaul, Spain, and Britain. The dioceses were governed some by prefects, some by proconsuls, and others by vicars. The provinces were under rectors. The government of the Christian religion, as established by Constantine, was in so far adapted to this division, and the term diocese and others passed over to ecclesiastical matters. At first, a diocese meant the collection of churches or congregations under the charge of an archbishop. The name came afterwards to be applied to the charge of a bishop, which had previously been called a parish. England and Wales are divided ecclesiastically into two provinces, viz., Canterbury and York, the former being presided over by the primate of all England and the latter by the primate of England; each of which is subdivided into dioceses, and these again into archdeacons, rural deaneries, and parishes. A diocese is synonymous with the see of a suffragan bishop.

**DIOCLETIANUS, VALERIUS**, b. in humble life near Salona, in Dalmatia, 245 A.D., inherited from his mother, Dioclea, the name of Diocles, which he afterwards enlarged into D., and attached as a cognomen to Valerius, a name of the most patrician associations. He adopted a military career, and served with distinction under Probus and Aurelian, accompanied Carus on his Persian campaign, and finally, on the murder of Numerianus having been discovered at Chalcedon, he was proclaimed emperor in 284 by the army on its homeward march. The suspected assassin of Numerianus, the prefect Arrius Aper, he slew with his own hands, in order, it is alleged, to fulfill a prophecy communicated to him, while still a lad, by a Druidess of Gaul, that he should accede to a throne as soon as he had killed an *aper* (wild-boar). In 285, D. commenced hostilities against Carinus (the joint-emperor along with the deceased Numerianus), who, although victorious in the decisive battle that ensued, was murdered by his own officers, thus leaving to D. the undisputed supremacy. His first years of government were so molested by the incursions of barbarians, that, in order to repel their growing aggressiveness, he took to himself a colleague—namely, Maximian—who, under the title of Augustus, became joint-emperor in 286. D. reserved for himself the charge of the eastern empire, and gave the western to Maximian. Still the attacks of the barbarians continued as formidable as ever. The empire was menaced by the Persians in the e., by the Germans and other barbarians in the w.; and in order to provide for its permanent security, D. subjected it to a still further division. In 292, Constantius Chlorus and Galerius were proclaimed as Cæsars, and the distribution of the Roman empire was now fourfold: D. taking the e., with Nicomedia as his seat of government; Maximian, Italy and Africa, with Milan as his residence; Constantius, Britain, Gaul, and Spain, with Trêves as his headquarters; Galerius, Illyricum, and the entire valley of the Danube, with Sirmium as his imperial abode. It was upon his colleagues that most of the burden of engaging actively in hostilities fell, as D. seldom took the field in person. Among the conquests, or rather re-conquests, that were made under his rule, may be enumerated that of Britain, which, after maintaining independence under Carausius and Allectus, was, in 296, restored to the empire; that of the Persians, who were defeated, and compelled to capitulate in 298; and that of the Marcomanni, and others of the northern barbarians, who were driven beyond the Roman frontier. D., after 21 years' harassing tenure of government, desired to pass the residue of his days in tranquillity. On the 1st of May, 305, accordingly, he abdicated the imperial throne at Nicomedia, and compelled his colleague, Maximian (much against the latter's will), to do likewise at Milan. D. sought retirement in his native province of Dalmatia, and for 8 years resided at Salona (see SPALATO), devoting himself to philosophic reflection, to rural recreation, and to horticultural pursuits. Two years before his abdication, he was instigated by his colleague, Galerius, to that determined and sanguinary persecution of the Christians for which his reign is chiefly memorable. He died in 313.

**DIODATI, JEAN**, a Swiss theologian, was b. in Geneva in 1576. He belonged to a noble Italian family, originally of Lucca. His progress in letters was so rapid, that Beza caused him to be appointed professor of Hebrew at the age of 21. In 1608, he became a pastor of the Reformed church, and in the following year, professor of theology. About this period, he endeavored to spread the doctrines of the reformation in Venice and other cities of Italy, but without success. In 1614, he went to Nîmes, where he preached for three years; and in 1618, he was sent to the synod of Dort, to represent the Genevese church. Here his talents were so highly estimated, that he was one of the divines appointed to draw up the articles of the synod. He died at Geneva in 1649. D. was a somewhat intolerant Calvinist; but as a preacher, he was eloquent, persuasive, and conscientious. His Italian translation of the Bible appeared in 1607; his French, in 1644. Among his other works may be mentioned his *Annotationes in Biblia* (1607); *De Fictitio Pontificiorum Purgatorio* (1619); and *De Justa Seccessione Reformatorum ad Ecclesiam Romanam* (1628).

**DIODON** (Gr. two-toothed), a Linnæan genus of fishes, now giving its name to a family, *diodontidæ* (*gymnodontes* of Cuvier), of the order *plectognathi*. The fishes of this family have no distinct teeth, but their jaws, which are shaped like the beak of a parrot, are covered with a substance like ivory, formed of the teeth consolidated together. This is reproduced as fast as it is worn away by use, and the mouth is admirably adapted for grinding down the crustaceans and sea-weeds on which these fishes feed. Their flesh is mucous, and that of some is regarded as poisonous. None of them are used for human food. Some of them, particularly of the genera *D.* and *tetraodon*, have a remarkable power of inflating their bodies by filling their stomachs with air, the stomach being extremely dilatible, and assuming a globular form when distended, whence they have received the name **GLOBE-FISH**, whilst from the spines, which stand out in all directions, like those of a hedgehog when rolled up, as if for defense of the inflated body, some of them have been designated **PORCUPINE FISH**. When distended with air, they float in the water with the back downwards but are not incapable of swimming in this position, as was formerly supposed. The *diodontidæ* are fishes of warm seas; one or two species, occasionally wafted by the currents to more northern shores, are among the rarest of British fishes.—The **SUNFISH** belongs to this family. The name *D.* has recently—with the effect only of confusion—been given to a new genus of cetaceous animals, of which one very rare species has occurred on the British coast.

**DIODORUS**, **SICULTS**, a Greek historian, was b. at Agyrium, in Sicily. Little is known of his life beyond what is told by himself. He lived in the times of Julius and Augustus Cæsar, traveled in Asia and Europe, and lived a long time in Rome, collecting the materials of his great work, the compilation of which occupied thirty years. This work, the *Bibliotheca* or Library, was a history of the world, in forty books, from the creation to the Gallic wars of Julius Cæsar. It was divided by the author into three parts—the first of which, in six books, comprises all the Greek and foreign myths down to the Trojan war; the second, in eleven books, contains the history from the year 1184 B.C. to the death of Alexander the great; the third, in twenty-three books, continues the narrative of events from that date to the year 60 B.C. Of the *Bibliotheca*, the first five books are extant entire; the next five books are wholly lost; the next ten are complete; and of the remainder of the work, considerable fragments have been preserved. Had *D.* possessed any powers either of criticism or of arrangement, his work would have been of the greatest importance; but he was in both respects so deficient, that his history has no practical value beyond what belongs to an immense mass of raw, and now scarcely available material. His narrative is colorless and monotonous, and his diction, generally clear and simple, holds a sort of middle place between the pure Attic and the colloquial Greek of his time. The best editions of *D.* are Wesseling's (Amst. 1746), the *Deux-ponts* (1793–1801), and Dindorf's (Leip. 1828–31).

**DIÆCIOUS** (Gr. *dis*, twice; and *oikion*, a habitation), in botany, a term applied either to plants or flowers, when not only the flowers but the individual plants are unisexual—i.e. when male and female flowers are produced upon separate plants. *D.* plants form a distinct class in the Linnæan sexual system; but in thus placing them apart, if the principle of arrangement had been strictly maintained, great violence would often have been done to natural affinities; *D.* species frequently occurring in genera and families usually *monæcious* (q.v.) or *hermaphrodite*, and also *monæcious* and *hermaphrodite* species in those which are usually *diæcious*. Familiar examples of *D.* plants may be seen in most species of willow. Amongst cultivated plants, hemp, spinach, and the date-palm may be instanced.

**DIOGÈNÈS**, the cynic philosopher, was a native of Sinope, in Pontus, where he was born about 412 B.C. His father, Icesias, or Ictas, by name, and a banker by occupation, was convicted of having swindled, and so the young *D.* had to leave Sinope. His youth had been that of a spendthrift and a rake; but on coming from Sinope to Athens, he became interested in the character of Antisthenes, by whom, however, his first advances were repelled. In spite of his inhospitable reception, *D.* renewed the attempt to find favor with Antisthenes; but though often driven away by blows, his perseverance at last prevailed; and Antisthenes, moved with compassion, consented to admit him as a pupil. *D.*, from being an extravagant debauchee, plunged into the opposite extreme of austerity and self-mortification. He would roll in hot sand during the heat of summer; in winter, he would embrace a statue covered with snow. His clothing was of the coarsest, his food of the plainest. His bed was the bare ground, whether in the open street or under the porticoes. His permanent residence (if such it could be called) was a tub, which belonged to the Metroon, or the temple of the Mother of the Gods. His eccentric life did not, however, cost him the respect of the Athenians, who admired his contempt for comfort, and allowed him a wide latitude of comment and rebuke. Practical good was the chief aim of his philosophy; for literature and the fine arts he did not conceal his disdain. He laughed at men of letters for reading the sufferings of Ulysses, while neglecting their own; at musicians who spent in stringing their lyres the time which would have been much better employed in making their own discordant natures harmonious; at savans for gazing at the heavenly bodies, while sublimely incognizant of earthly ones; at orators who studied how to enforce truth, but

not how to practice it. He was seized by pirates on a voyage to Ægina, and carried to Crete, where he was sold as a slave. When asked what business he was proficient in, he answered: "To command men." His purchaser was Xeniadēs of Corinth; but the slave soon came to rule the master, acquired his freedom, was appointed tutor to the children, and spent his old age as one of the household. It was here that he had his interview with Alexander the great. The king opened the conversation with: "I am Alexander the great," to which the philosopher answered: "And I am Diogenes the cynic." Alexander then asked him in what way he could serve him, to which D. rejoined: "You can stand out of the sunshine." Alexander is said to have been so struck with the cynic's self-possession, that he went away, remarking: "If I were not Alexander, I should be Diogenes." In spite of his early excesses and his subsequent privations, D. lived at Corinth till 323 B.C., when he died, at the age of 90.

**DIOTENES OF APOLLONIA**, flourished in Athens about 460 B.C. He was a pupil of Anaximenes, and a contemporary of Anaxagoras. He believed air to be the source of all being, and all other substances to be derived from it by condensation and rarefaction.

**DIOTENES LAERTIUS**, the author of a biographical history of the Greek philosophers, seems to have been born at Laerta, in Cilicia, and to have taken his surname from that town. So little is known of his personal history, that the very age in which he flourished is a matter of doubt. By some it is assigned to the end of the 2d, and by others to the middle of the 3d c. after Christ. His name has been kept alive by his *Lives of the Philosophers*, a work which contains a great mass of interesting information regarding the private lives and habits of the most eminent philosophers of antiquity. Though the work is utterly worthless in respect of plan, coherence, or criticism, it yet contains so many piquant anecdotes, and so many valuable quotations from lost works, that Montaigne's wish was perhaps a justifiable one—that instead of one Laertius, we had had a dozen. The best edition of Laertius is that of Hübner, 2 vols. 8vo (Leip. 1828–31).

**DIOMEDEA**. See ALBATROSS.

**DIOMEDE ISLANDS**, a group about the middle of Behring's strait, form, as it were, a number of stepping-stones between the most easterly point of Asia and the most westerly of America. Their names are Fairway, Crusenstern, and Ratamanow; and their central point is in lat. 65° 46' N., and long. 168° 55' west.

**DIOMEDES**, the bravest, after Achilles, of all the Greeks who took part in the Trojan war. His exploits occupy a prominent place in the record of the heroic deeds sung by Homer in the *Iliad*. He vanquished in fight Hector and Æneas, the most valiant of the Trojans; and even Mars and Venus, when they took the field on the Trojan side, were attacked and wounded by him. In the games instituted by Achilles in honor of Patroclus, he gained the prize in the chariot-race, and worsted the mighty Ajax in single combat. Along with Ulysses, he carried off the Palladium, on which the fate of Troy depended. On returning to Argos (to the crown of which he had succeeded after the death of Adrastus), he found that his wife had proved unfaithful in his absence. Leaving home, he went, according to one tradition, to Italy, where he took part with the Trojans against Turnus. Several cities on the southern shores of that country claimed to have been founded by him.

**DIOMEDES**, son of Mars and Cyrene, king of the Bistones in Thrace. It was this Diomedes, and not the Trojan hero, who fed his mares upon human flesh. After he was slain by Hercules, the mares had the pleasure of eating their master.

**DION OF SYRACUSE**, 408–353 B.C.; brother-in-law of Dionysius the Elder; an admirer and pupil of Plato. Because of his stern moral character Dion became odious to the king, who banished him, confiscated his property, and gave his wife to another man. Dion made war upon Sicily and defeated the tyrant, but was soon supplanted by the intrigues of Heraclides and again banished. He was recalled soon afterwards, but the people complained of his tyrannical conduct, and he was assassinated.

**DION CASSIUS COCCEIANUS**, a celebrated Greek historian, was b. at Nicæa, in Bithynia, 155 A.D. He held various high offices of state under the Roman emperors, was twice consul, and enjoyed the intimate friendship of Septimius Severus. He is best known by his *History of Rome*, in 80 books, of which only 18 (from the 36th to the 54th) have reached us complete. The others are only known to us from fragments and abridgments. His high position gave him free access to the national archives, and as an authority on some points, especially on the imperial epoch of Roman history, his work is not without very considerable value. He wrote on the model of Thucydides, to whom, indeed, he is far inferior, both in vigor of judgment and acuteness of criticism; yet many passages of his History might be quoted as among the best samples of the rhetoric of the age in which he lived. D. died at Nicæa, but the date of his death is not known. The best edition of his History is that of Sturz (Leip. 1824–43).

**DION CHRYSOSTOMUS** (Golden-mouthed), an eminent Greek rhetorician, was b. at Prusa, in Bithynia, towards the middle of the 1st century. His father, Pasocrates, paid great attention to his education, which was also enriched by travel. D., after residing for some time in his native town, came to Rome, where, however, he had the mis-

fortune to excite the suspicion of the emperor Domitian, and was in consequence obliged to flee. On the accession of Nerva, 96 A.D., he returned to Rome, and was honorably received. Nerva's successor, Trajan, held D. in the highest estimation, even permitting him to ride beside himself in the imperial chariot. His excellent disposition procured him many friends, while his remarkable powers of oratory excited universal admiration. He died at Rome about 117 A.D. D. left a very great number of orations, of which 80 are still extant in whole, with fragments of 15 others. They discuss questions in politics, morals and philosophy, and are written in pure Attic Greek. According to Niebuhr, he was "the first writer after Tiberius that greatly contributed towards the revival of Greek literature." Good editions of D.'s orations are those of Reiske (Leip. 1784), Emperius (1844), and L. Dindorf (1857).

**DIONÆA**, a very curious and interesting genus of plants of the natural order *droseraceæ*, having a 5-partite calyx, 5 petals, 10 to 20 stamens, and one style, with 5 closely united stigmata. Only one species is known, *D. muscipula*, sometimes called **VENUS'S FLY-TRAP** and the **CAROLINA CATCHFLY PLANT**. It grows in marshy places in the warmer parts of North America, as far n. as North Carolina, and is a perennial plant, with a rosette of root-leaves, from the midst of which arises a leafless stem (scape) about 6 in. high, terminating in a corymb of white flowers. It is remarkable for the irritability of its leaves. The leaf-stalk is elongated, winged, and leaf-like, and bears at its extremity an orbicular leaf, set round at the margin with stiff hair-like "spines," and having on its upper surface many small glands, and three delicate irritable hairs on each side, so placed that an insect can hardly traverse the leaf without touching one of them, when the two sides of the leaf immediately fold together upon it, and lay hold of it, the marginal bristles crossing one another, and preventing the possibility of escape. The leaf does not open again till the whole substance of the insect has been absorbed by the plant, and nothing but the skeleton of the captive remains. For this purpose, the plant exudes a secretion of a character somewhat similar in its digestive properties to pepsine; and under the influence of this, the material of the insect capable of yielding nourishment to the plant, is digested, and ultimately absorbed by the same glands that secreted the fluid. This process of digestion and absorption sometimes occupies three weeks.—See *Insectivorous Plants*, by Charles Darwin (1875).

**DIONYSIA**, feasts of Bacchus, celebrated especially in Attica. The lesser Dionysia were held in country places in Dec., when the vine was grown. There was a vintage festival, songs, dances, impromptu plays, a phallic procession, and rustic sports. The greater Dionysia were held in Athens in Mar., as a festival of joy for the departure of winter and the promise of summer. The ancient image of the god was conveyed from one sanctuary to another, with a chorus of boys and a procession wearing masks and singing odes. The festival culminated in tragedies, comedies, and satiric dramas, in the great theater of Dionysus.

**DIONYSIUS, THE AREOPAGITE**, is mentioned in the Acts of the Apostles (chap. xvii., verse 34) as one of the few persons in Athens converted to Christianity by Paul. A history has been invented for him by the church. It is said that he was in Egypt when the crucifixion happened, and observing the eclipse that accompanied it, exclaimed: "Either God himself is suffering, or he sympathizes with some one who is suffering." At the time when Paul visited the metropolis of Greece, D. was a member of the council of the Areopagus, whence his name. Tradition also declares that the apostle installed him as the first bishop of Athens, and that he suffered the fate of a martyr. The writings which are falsely current under his name treat of such topics as the heavenly hierarchy, the names of God, the ecclesiastical hierarchy, etc. Their theology is of the mystical kind. The style, contents, and historic allusions clearly indicate that the author of these writings could not have flourished before the close of the 5th c., and, in fact, the writings first made their appearance in the 6th century. Dazzling neoplatonic phantasies concerning the divine essence, angels, and holy spirits, splendid descriptions of the ceremonies of the Catholic worship, glorifications of the priestly hierarchy, panegyrics on monastic life, and mystical interpretations of church doctrine, made the works immensely attractive, especially to the Greek monks, whose manner of life was preeminently contemplative. According to a recent hypothesis, the so-called writings of D. are the composition of some Christian Platonist, who, in opposition to the not yet wholly extinguished Gnosticism, sought to incorporate with Christianity the forms, ideas, and ceremonies of the Dionysian (Bacchic) mysteries. The translation of the work into Latin by Scotus Erigena, in the dawn of the middle ages, gave a new impulse to monasticism in the western church, and may be almost said to have created its mystic theology. The *Areopagitic theology* was, in fact, the name given during the middle ages, and even as late as the 18th c., to that mystical method of apprehending religious truth made current by the writings ascribed to D., and afterwards formally introduced into Latin Christianity by Hugo St. Victor in the 12th century. This theology proceeds upon the principle, that the divine spirit is indispensable even to the understanding of man.

**DIONYSIUS, THE ELDER**, tyrant of Syracuse, was b. 431 or 430 B.C. He was originally a clerk in a public office, but manifested at an early period a passion for political and military distinction. When the Agrigentines, after the conquest of their city by

the Carthaginians, accused the Syracusan generals who had failed to relieve them of treachery, D. supported their accusations before the people of Syracuse, and induced the latter to appoint new commanders, of whom he himself was one. But in a very short time he supplanted his colleagues also, and, when only 25 years of age, made himself, by the help of his mercenaries, absolute ruler of the city. To strengthen his "tyranny" (the name given by the Greeks to any *usurped* authority, however wisely and beneficently exercised), he married the daughter of Hermocrates, the late head of the aristocratic party, and thus attached the followers of that leader to himself. After he had fiercely suppressed several insurrections, and conquered some of the Greek towns of Sicily, he made preparations for a great war with the Carthaginians. It broke out 397 B.C. At first, fortune favored D., but after a short time he suffered a series of reverses, so calamitous, that all his allies abandoned him, and he was shut up in the city of Syracuse, apparently without hope of escape. When he was about to fall a victim to despair, a pestilence broke out in the Carthaginian fleet. D. took courage, and suddenly attacking his enemies by land and sea, obtained a complete victory. In the years 393 and 392 B.C., the Carthaginians renewed hostilities, but were defeated on both occasions, and D. was enabled to conclude a most advantageous peace. He now turned his arms against lower Italy, and in 387 B.C., after a siege of 11 months, captured Rhegium. From this time he continued to exercise the greatest influence over the Greek cities of lower Italy, while his fleets swept the Tyrrhenian and Adriatic seas. But D. was not contented with the reputation of being the first warrior and statesman of his age; he wished to shine as a poet also. He even ventured so far as to contend for the prize at the Olympic games, and about the end of 388 B.C., sent thither a splendid embassy, comprising the best reciters of the time, whose utmost skill, however, could not induce the judges to decide in his favor. D. was more successful at Athens, where he several times obtained the second and third prizes for tragedy, his last production even obtaining the first. He also invited many poets and philosophers to his court, his treatment of whom, however, was not always courteous. In 368 B.C., he renewed the war with the Carthaginians, whom he wished to drive out of Sicily altogether, but died in the following year, before he could accomplish his design. It was rumored that his death was hastened by his physician, at the instigation of his son. D. was unquestionably a most vigorous ruler, but unscrupulous as to the means he employed to secure his ends, and tormented in his last years by the suspicion that he was surrounded with traitors.

**DIONYSIUS, THE YOUNGER**, son of the preceding, celebrated his entrance into public life, 367 B.C., by a splendid festival, which lasted ninety days. His political education had been designedly neglected by his father, and in consequence he grew up an indolent, pleasure-loving, and dissolute prince. Dion, a relative of his father, sought to improve him by the instructions of Plato, but his endeavors were frustrated by Philistus, the historian, who disgracefully encouraged the excesses of the youth. Dion was banished, but afterwards returning to Sicily, expelled D. from Syracuse. The latter fled to Locri, the birthplace of his mother, Doris, where he was hospitably received. He repaid the kindness of the Locrians by making himself master of their city, which he ruled despotically for several years. In 346 B.C., the course of events enabled him to return to Syracuse, but he could not firmly re-establish himself. His cruelties drove the citizens to ask the aid of the Corinthians against him. Timoleon was sent to their assistance, and D., shut up in the citadel of Syracuse, was compelled to surrender, 343 B.C. He was brought to Corinth, where he soon squandered the wealth which he had carried away from Sicily, sunk into obscurity, and died in extreme poverty.

**DIONYSIUS, OF ALEXANDRIA, SAINT**, d. 265 A.D., at Alexandria, where he was born. He was of a noble pagan family, but was an early convert to Christianity, and under the tutelage of Origen became a priest, and chief of the Alexandrian school of theology. In 247, he became a bishop. In the persecution of Decius, about this time, he was arrested and condemned to death, but was rescued by peasants, and remained concealed for a year in the Libyan desert. In 257, he was again exiled, but restored three years later. He was a voluminous writer, but most of his works are lost.

**DIONYSIUS, OF HALICARNASSUS**, a learned critic, historian, and rhetorician, was the son of one Alexander of Halicarnassus, and was b. probably about the middle of the century before Christ. He came to Rome at the termination of the civil wars, 29 B.C., and resided there for 22 years, familiarizing himself with the language, literature, and antiquities of the Romans. His death occurred shortly after 7 B.C. D.'s most valuable work is unquestionably his *History of Rome*, although it does not exhibit the finest qualities of his mind. The author was an admirable rhetorician, but had very little political discrimination, and no perception of the difference between a myth and a historic fact. Yet, inasmuch as it contains a mine of information about the constitution, religion, history, laws, and private life of the Romans, it will always command the regard of scholars. Of the 20 books of which it originally consisted, we possess only the first 9 in a complete form, the 10th and 11th nearly so; and of the rest, only a few fragments. The first edition of the Greek original was that by Stephens (Paris, 1546), but a very good Latin version was published as early as 1480. Angelo Mai

published (Milan, 1816) a collection of the fragments of the lost books from a MS. in the library at Milan, the genuineness of which has been doubted by Niebuhr. The rhetorical and critical works of D. are of the highest literary merit. The principal are his *Censura Veterum Scriptorum*, his *Ars Rhetorica*, and his *De Compositione Verborum*. The first complete edition of the history (or Archaeologia, as D. called it) and rhetorical works was that of Fr. Sylburg (Frankfort, 1586); one of the best is that of Reiske (6 vols., Leip., 1774-77).

DIONYSIUS, or DENIS, 1261-1325; King of Portugal, son of Alfonso III., whom he succeeded, 1297. He married Elizabeth of Aragon. His reign was wise and just, and the beneficial reforms he instituted gained him the title of "father of his country." He built cities and fortifications, and founded the university of Lisbon, the only one in the kingdom.

DIONYSIUS EXIGUUS, a Roman monk of the 6th c., a native of Scythia. He was the compiler of the first regular ecclesiastical code for the western church. He is more widely known in chronology as the founder of the "Dionysian Era" which was observed by Christians for more than a thousand years. Before this the Christian era had started from the death of Christ; he fixed it as nearly as possible at the time of the birth.

DIONYSUS. See BACCHUS, *ante*.

DIOPHANTINE ANALYSIS is that section of the theory of unlimited or indeterminate problems which attempts to find rational and commensurable values answering to certain equations between squares and cubes. This class of problems was first and chiefly treated of by Diophantus (q.v.), who has given his name to the theory of their solution. We shall not here attempt to explain the nature of the analysis, which is very subtle, and guided by few general rules. The difficulties of the solution of diophantine problems in most cases fail to be overcome by the skill and ingenuity of the analyst. We confine ourselves to stating the following examples of the problems solved by the D. A.: 1. To find 2 whole numbers the sum of whose squares is a square. 2. To find 3 square numbers in arithmetical progression. 3. To find a number from which 2 given squares being severally subtracted, each of the remainders may be a square.

DIOPHANTUS, a distinguished Greek mathematician, lived at Alexandria, according to some, about the middle of the 4th c.; according to others, about the close of the 5th. His name first occurs in the life of Johannes Damascenus, written by John, patriarch of Jerusalem, in the 8th century. He is commonly represented as the inventor of algebra, but he himself speaks of that science as known before his time. It is possible he may have been acquainted with Hindu algebra; at all events, according to De Morgan, there is a very great similarity between the Hindu algebra and that of Diophantus. He occupied himself chiefly with the class of problems characterized in the preceding article. Of his valuable work, the MS. of which was discovered in the 10th c., *Arithmetica*, consisting originally of 13 books, only 6 have been preserved. Besides this we possess a book on polygonal numbers. The best edition is that of Fermat (Toulouse, 1670); there is a German translation by Schulz (Berl. 1821).

DIOPSIS, a genus of dipterous insects of the same great family with the house-fly, remarkable for the prodigious prolongation of the sides of the head, so as to form stalks for the eyes, which are thus removed to a distance from the body of the insect, almost equaling in some species the length of its wings. All the species are found in warm parts of the old world.

DIOPTRICS is that branch of geometrical optics (see OPTICS) which treats of the transmission of rays of light from one medium into another, differing in kind. It consists of the results of the application of geometry to ascertain in particular cases the action of what are called the laws of refraction. When a ray of homogeneous light is incident upon a surface, the angle which its direction makes with the normal or perpendicular to the surface at the point of incidence is in D., as in catoptrics, called the angle of incidence. The angle which the refracted ray makes with the same line is called the angle of refraction. This being premised, we may state the laws of refraction. 1. The incident and refracted ray lie in the same plane with the normal, at the point of incidence, and on opposite sides of it. 2. The sine of the angle of incidence, whatever that angle may be, bears to the sine of the angle of refraction a constant ratio dependent only on the nature of the media between which the refraction takes place, and on the nature of the light. According to the second law, if we call the angle of incidence  $i$ , and that of refraction  $r$ , we shall have  $\sin i = \mu \sin r$ , where  $\mu$  is a quantity depending upon the nature of the media and of the light. It will have, for instance, a certain value for refraction from vacuum into glass, another from glass into water, and so on; also, it will have one value for red light, another for green, and so on. The quantity  $\mu$  is called the refractive index, and is greater than 1 when refraction takes place from vacuum into a medium, and in general is greater than 1 when the refraction

is from a rarer into a denser medium, and less than 1 when the opposite is the case. In D., the laws of refraction may be considered as depending for their truth upon experiment; in physical optics, they are deductions from an hypothesis respecting the constitution of light. They are not merely approximately true; they are absolute physical laws.

Before proceeding to consider the simpler leading cases of refraction, one or two interesting propositions in dioptrics require to be explained.—1. If the refractive index for a medium, when light is incident upon it from vacuum, be  $\mu$ , and the index for another medium, under the same circumstances, be  $\mu'$ , then, when light proceeds from the second medium into the first, the refractive index is  $\frac{\mu}{\mu'}$ . The proof of this proposition depends upon the two following experimental laws: (1.) If a ray of light proceed from a point to a second, suffering any reflections or refractions in its course, then, if it be incident in the reverse direction, i.e., from the second point, it will follow the exactly reverse course to the first point. This is proved by experiment, but may be accepted as axiomatic. (2.) If a ray pass from vacuum through any number of media, having their faces plane and parallel, when the ray emerges into vacuum its direction will be parallel to that which it had before incidence. To deduce the proposition from these laws, let  $i$  be the angle of incidence from vacuum upon the first medium,  $r$  the angle of refraction, which will also be the angle of incidence upon the second medium. Also let  $r'$  be the angle of refraction into the second medium, which will also be the angle of incidence upon the second bounding surface. By the second of the preceding experimental laws, the angle of emergence into vacuum will be  $i$ . Hence we shall have by the first of these laws,  $\sin i = \mu' \sin r$  at the first surface, and  $\sin i = \mu \sin r'$  at the second. From these equations, we have  $\sin r = \frac{\mu}{\mu'} \sin r'$ , which proves the proposition.

It follows that if  $\mu$  be the refractive index from vacuum into a medium, that from the medium into vacuum will be  $\frac{1}{\mu}$ .—2. Our second proposition relates to what is called the *critical angle*. If  $i$  be the angle of incidence of a ray within a medium, the refractive index of which is  $\mu$ , and  $r$  the angle of refraction into vacuum, then we have from the former proposition  $\sin i = \frac{1}{\mu} \sin r$ . From this formula, if  $i$  be given,  $r$  may be found,

and a real value will be given to  $r$  so long as  $\sin i$  is  $\leq \frac{1}{\mu}$ ; but when  $i$  has a value greater than that determined by the equation  $\sin i = \frac{1}{\mu}$ , the formula fails to give us a value of

$r$ , for the sine of an angle cannot be greater than 1. And experiment shows that, in fact, there is no refracted ray when the angle of incidence is greater than that above assigned, the ray being wholly reflected within the medium. The angle of which the sine is  $\frac{1}{\mu}$  is called the *critical angle*. For glass, it is about  $41^\circ 45'$ ; for water, about  $48^\circ 30'$ . This angle is sometimes called the angle of *total reflection*. In internal reflection at the surfaces of media, the reflected light is more nearly equal in intensity to the incident than in any other case of reflection. While it thus appears that refraction from a denser into a rarer medium is not always possible, it may be added, that it is always possible from a rarer into a denser.

We shall now investigate some simple cases of refraction. 1. And first of refraction at a plane surface. Let DIMN (fig. 1) be any medium bounded by a plane DI, and let R be a radiant point, and RD and RI two incident rays of a divergent pencil proceeding from R to the surface of the medium; then RD being perpendicular to the surface, suffers no refraction, but proceeds along DM within the medium; but RI is refracted in the direction IN, which, produced outwards, meets the normal DF in F. Therefore, a small pencil of rays proceeding from R, and having RD, perpendicular to the surface, for axis, will be refracted into another pencil diverging from the imaginary focus F; for all the rays intermediate between RD and RI will converge very near F when the pencil is small. An eye within the medium, and between N and M, would thus, the pencil being small, see the luminous point R, as if it were at F, or further off than it really is. In the opposite case, in which the luminous point is within the refracting medium, similar reasoning shows that after the rays emerge from the plane surface into the air, they will, if the pencil be small, appear to proceed from an imaginary focus nearer to the surface than the luminous point.

2. The case of refraction through a prism, which we are next to consider, is, in fact, the case of refraction through a medium bounded by plane surfaces which are not parallel. Conceive two planes at right angles to the plane of the paper, and making on

FIG. 1.

that plane the figure BAC (fig. 2). The question is as to the laws of transmission of a ray, SPQR, of homogeneous light through the prism. Draw  $mn'$  and  $n'n$  perpendicular to the sides. Then  $n'PQ$  and  $n'QP$  are respectively the angles of refraction at the first, and of incidence at the second surface. Now, as  $n'QA$  and  $n'PA$  are each of them right angles, and as all the angles in the figure  $n'QAP$  are equal to four right angles, it follows that the angles at  $n'$  and at  $A$  together are equal to two right angles. But the angle at  $n'$ , together with the angles  $n'PQ$  and  $n'QP$ , are equal to two right angles; therefore must the angles  $n'PQ$  and  $n'QP$  together be equal to the angle at  $A$ . In other words, in refraction through a prism: *The sum of the angles of refraction at the first surface, and of incidence at the second, is equal to the angle contained between the plane sides of the prism.* From

FIG. 2.

this it might be shown, that the deviation of a ray caused by passing through a prism is always towards the thicker part of the prism, if the medium be denser than the surrounding atmosphere. It is a geometrical proposition which the student may solve for himself, that if  $i$  be the angle of incidence at the first surface, and  $e$  that of emergence at the second, and if  $\alpha$  be the angle of the prism, then  $\sigma$ , or the change of direction of the ray in its passage, is obtained from the formula  $\sigma = i + e - \alpha$ .

3. We now take up the case of refraction at a single spherical surface of a medium denser than the surrounding air. And first, of parallel rays refracted at a convex spherical surface. Let ABQP (fig. 3) be the refracting medium, whose terminating convex surface is spherical, C being the center of the surface, and V its vertex. Let XV be the axis of a pencil of parallel rays, of which any ray, RI, is incident at I. Then, if CIN be a normal, the angle of refraction, CIF, will be less than the angle of incidence, RIN, and the refracted ray will thus turn towards the axis, and meet it at some point, F. When the pencil is small, or the aperture, AVB, of only a few degrees, the rays will clearly nearly all converge to the same point, F. To find the position of F, we have, in the triangle ICF, the angle  $CIF = r$ , the angle of refraction, and ICF, the supplement of ICV or NIR (by parallel lines), i.e., of  $i$ , or the angle of incidence. Therefore, IF is to CF ::  $\sin i$  is to  $\sin r$ . And as for a very small pencil, IF may be taken = VF, we have  $FV : FC :: \sin i : \sin r$ , or ::  $\mu : 1$ . And putting  $FV = F$ , the principal focal distance, and  $VC = R$ , we have  $F = \frac{\mu}{\mu - 1} R$ . If the medium be crown-glass, for

FIG. 3.

which the value of  $\mu$  is  $\frac{3}{2}$ , we have  $F = \frac{\frac{3}{2}}{\frac{3}{2} - 1} R$ , or  $F = 3R$ ; i.e., the principal focal distance is equal to three times the radius of the sphere. The student may, by similar reasoning, ascertain for himself the focus of parallel rays incident on a concave spherical refracting surface, as also the focus in the case of a pencil of parallel rays within the medium and emerging from it. The case of a divergent pencil is incapable of such elementary treatment as to justify its insertion here. For branches of the subject treated under separate heads, the reader should refer to the articles CAUSTIC, LENS, and REFRACTION. Under REFRACTION, he will find a table of the values of  $\mu$ —the refractive index for various media and kinds of light. See also the articles SPECTRUM and CHROMATICS.

# DIORAMA. See PANORAMA.

**DIOSCOREA CEÆ**, a natural order of plants, of which the genus *dioscorea* (see YAM) is the type. They are twining shrubs, with large tubers, either above or below ground. They are generally classed with endogenous plants; they are among the *dictyogens* of Lindley. There are about 120 known species. The most important plants of the order are the different species of *dioscorea* or yam (q.v.). Black bryony (q.v.) is its only representative in the British flora. *Testudinaria elephantipes*, a s. African species, sometimes called *elephant's foot*, and *Hottentots' bread*, has a large fleshy rhizome, with a rough cracked bark, which is used as food by the Hottentots in times of scarcity.

**DIOSCORIDÉS**, PEDANIUS, or PEDACIUS, a Greek physician, was a native of Anazarba, or Anazarbus, in Cilicia, and flourished in the 1st or 2d c. of our era. He accompanied the Roman armies as physician through many countries, and collected a great store of information and personal observation on plants. In his great work, *De Materia Medica*, he treats of all the then known medicinal substances and their properties, real or reputed, on the principles of the so-called "humoral pathology." Two other works bear the name of D., but their genuineness is very questionable. During 15 centuries, D. maintained undisputed authority in botany and in materia medica, an authority which he still holds among the Turks and Moors. The best editions

of D. are by Saracenus (Frankf. 1598) and Sprengel (2 vols., Leip. 1829). The *De Materia Medica* has been translated into the Italian, German, French, and Spanish languages. There is also an Arabic translation in MS. in various libraries of Europe.

**DIOSCORIDES PEDANIUS**, a Greek botanist of about the 2d or 3d c. after Christ. He traveled far and wide studying plants, and wrote a famous work on their nature and medicinal qualities. The work is still held in high esteem.

**DIOSCURI**. See GASTOR AND POLLUX, *ante*.

**DIOSMA**. See BUCKU.

**DIOSPYROS**. See DATE PLUM and EBONY.

**DIP**, in geology, is the inclination of strata downwards into the earth. The amount or angle of dip is the degree of deviation from a level line, or the plane of the horizon. The point of dip is the point of the compass to which the dip is inclined.

**DIP OF THE HORIZON**, the angle comprehended between two lines drawn from the point of observation, one horizontal, the other a tangent to the surface of the sea; the apparent angular depression of the visible horizon.

**DIPHTHERIA**, or DIPHTHERITIS (Fr. *diphtherite*, from Gr. *diphthera*, a pellicle), a name first applied by M. Bretonneau of Tours, a distinguished French physician, to a form of very fatal sore throat occurring epidemically, chiefly in children, and apt to be confounded both with croup (q.v.) and with malignant sore throat (*angina maligna*), as it is found in connection with scarlet fever (q.v.). Diphtheria is distinct from both these diseases, not only in its symptoms, but in the character and position of the morbid changes on the mucous membrane. In croup, there is a pellicular membrane, indeed, but it is almost confined to the air-passages, and centers in the larynx (q.v.); in diphtheria, it usually begins in the pharynx or back of the throat, and often extends down the esophagus, or gullet. Croup is also a much more decidedly inflammatory disease than diphtheria. Malignant or ulcerative sore throat has even less in common with diphtheria; for in the latter there is no ulceration in the majority of cases, the mucous membrane being merely covered over with a more or less thick veil of false membrane; in both affections, however, there is enlargement of the glands behind the ear and in the neck, generally in the neighborhood of the parts internally affected. The throat affection in diphtheria is often accompanied by a very low and dangerous form of fever, with great and rapid loss of the patient's strength, which is still further reduced of course by the inability to take food; in other cases, the disease is fatal by suffocation, and tracheotomy has been performed (in some few instances successfully) to relieve the patient from impending death. After the acute disease is over, the recovery may be delayed by paralytic symptoms of various kinds; or simply by extreme debility, with exhaustion and loss of appetite. Diphtheria was supposed by Bretonneau to be contagious, but it is doubted by many whether the evidence of contagion is sufficient. There is no good evidence of any specific cure. The use of the tincture of muriate of iron in large doses (fifteen to twenty drops frequently repeated) has been recommended; also various disinfectants and caustics applied to the throat, as nitrate of silver, hydrochloric acid mixed with honey, and latterly Condy's disinfecting fluid; but all of these have also frequently failed in the hands of experienced physicians. Diphtheria does not appear to be so much under the influence of known sanitary conditions as other epidemics; at least its modes of origin and diffusion are still extremely uncertain.

**DIPHTHERIA**, or DIPHTHERITIS (*ante*). This is really a very old disease with a modern name, unfortunate because misleading, and the cause of much inefficient treatment. By many the disease has been regarded as a local more than a general affection, but within the last twenty years thorough study has revealed its nature and causes so that few things are more certain than that it has for many centuries been one of the dangerous diseases of the human race. That its characteristics were always precisely what they now are is not probable, because the sanitary condition of the world centuries ago, when devastating plagues swept the face of the earth, would be likely, especially when large numbers of human beings were collected together, to give this disease a more general inflammatory and malignant character. The causes which are now known to produce the disease have always been present wherever the human family has congregated in numbers, and wherever even a few have lived together without regard to cleanliness. It is thought that descriptions of the disease can be traced to a time anterior to Hippocrates (460 B.C.), and there is no doubt of its identity with that described by Aretæus of Cappadocia (100 A.D.), who called it *Ulcus Syriacum* and also *Malum Egyptianum*. Several other ancient authorities describe it, but during the dark ages little is recorded that is trustworthy. One of the earliest treatises upon it in modern times was by Hecker, who gives an account of an epidemic which prevailed in Holland in 1337. Besides the names given it by Aretæus, it has been called *cynanche maligna*, *cynanche gangrenosa* (*cynanche* means, literally, "dog-choke"), putrid fever, malignant inflammation of the pharynx, and putrid sore throat. The last name was the one adopted by the celebrated Dr. John Fothergill in his description of the epidemic which appeared in London in 1745. Some have contended that the disease which he described was malignant scarlet fever, but so accurate an observer and great physician as Dr. Fothergill, drawing the distinctions, as he does, between the diseases, could not

have been mistaken. His treatise, published in his works, is in many respects unexcelled. Of course some of the remedies now found most efficient were either not then known, or not obtainable in their best form, but his general treatment was more rational than much of more modern date; indeed it was not greatly different from that which an experienced physician of the present day would employ if limited to the remedies which were then available. The disease is well described by Dr. Samuel Bard of New York, in the first volume of the Transactions of the American philosophical society, in the review of an epidemic which appeared in 1771. The disease did not again attract the special attention of writers until 1818, when Bretonneau published his opinions and gave it the name under which it is now generally known, claiming, in his first papers upon the subject that the disease was at first local, and that the constitutional affection resulted from infection propagated by the local disease. The origin of diphtheria was ascribed by Vogel to the development of a microscopic organism, the *oidium albicans*, but this is also largely developed in Thrush, and is present in various diseased conditions of the mouth and throat. The present doctrine is, simply, that the disease is caused by certain disease germs, but what they precisely are has not been determined. This much is certain—D. is a septic disease, never found where no septic origin can be assigned. Feculent matter, passing through stages of putrefication and fermentation, such as obtains in sewers, cess-pools, and vaults of privies, and all manner of conduits or receptacles of waste matter, and the effluvia engendered in piles and masses of garbage, or of human or animal excrement, are the now recognized causes of diphtheria. Wherever these causes are constant, there the disease is constantly developed and is *endemic*. The only apparent exception to this is that at certain seasons of the year putrescent and feculent matter is liable to develop other diseases, when D. may occupy a more or less subordinate place. Again, there may be times when the septic causes are in abeyance; but when they become active, the disease becomes *epidemic* if the air is sufficiently impregnated with the infectious germs. In regard to the question of contagiousness or infectiousness, the following may be said, premising, however, a few words explanatory of these terms. In many respects contagiousness and infectiousness are synonymous, and some writers use only the former word. But there is this difference—such diseases as scarlet fever and small pox are contagious, and they are communicated through the air as well as by contact. There are other diseases which are contagious only by contact, as the itch. It would be more correct to call itch an infectious disease. Most other diseases which are communicated in the same manner are infectious. It appears, therefore, that there is some confusion in the use of the terms, and it is for this reason that some authorities use only the word contagious. But there are two distinct modes, and some diseases are communicated only by one of these modes; and if we desire to express the difference, the employment of the two terms is convenient, but care should be taken to distinguish clearly what idea it is intended to convey. If D. be a communicable disease, but not in the same manner as scarlet fever, we distinguish the difference by calling the former an infectious disease; and that D. has been communicated by contact there is no reasonable doubt. There have been many instances when diphtheritic expectorations have communicated the disease by being projected into the mouth or eyes of the attendant. Bretonneau and others maintained this. It is a matter of dispute as to whether exposure to the air breathed by patients having the disease is capable of communicating it, but the great mass of authority is now on the side of the affirmative. What is the explanation of this disagreement? The poison of D. is a species of ferment, and like many other ferments, it requires a certain quantity to produce a given effect. The contagious virus of small-pox is different; the minutest quantity, when inhaled, or when introduced by vaccination, being sufficient to propagate itself throughout the system, and there seems to be no provision of nature for its elimination until a crisis is reached. The poisonous principles which propagate some other diseases, when taken into the system do not need to ripen before they are again cast out; the excretory action of the animal economy sometimes removes them as fast as they are received. It is because of this conservative power, this action of the *vis medicatrix nature*, that mankind, as well as the lower animals, have been enabled to exist. We are all the time taking poisons into our bodies, and it is one of the offices of the various organs to remove them by the various processes of excretion. The poisonous principle of ordinary intermittent fever, if received only in small quantities, is readily disposed of, and the system retained in a healthy condition, but if the malarial poison be absorbed faster than it can be carried away, there results a series of morbid phenomena characteristic of this periodical disease. And so it is, most probably, with diphtheria; if the air of a sick-room be loaded with the effluvia from the breath and perspiration of a person laboring under a violent case of the disease, one who should remain in the room only a few moments, would be likely to receive enough germs of the disease to cause a manifestation of its presence, and if he were to remain a considerable time there would be danger of a serious attack. On the contrary, if the case were a mild one, or if the sick-room were well ventilated and disinfected, and the visitor were in good health, the danger would be slight. It is these varying circumstances which have caused a difference of opinion between different physicians; but the weight of evidence supports the opinion that D. is both contagious and infectious, and in a late work, Drs. Pepper and Meigs of Philadelphia give this as their conclusion.

Although diphtheria (or putrid fever, a more appropriate name, and comprehensive of all the phases of the disease) is eminently a constitutional affection, it is liable to special local manifestations, the latter sometimes apparently predominating. Now, why does it so often have predominating local characteristics? The following is probably the explanation. The attack is usually brought on by a "cold," and if the system be only slightly contaminated at the time, the symptoms are not likely to be alarming, and will readily yield to prompt treatment, but it should always be borne in mind that the disease is exceedingly stealthy and treacherous, and to be watched like a wolf. Again, the system may be considerably loaded with the germs of the disease, although not to the culminating point. Here, also, causes which produce a "cold" will, besides bringing on the general attack, also give rise to violent local symptoms. But when no exciting causes occur to hasten the attack, and the septic poison is being constantly received, there comes at last a time when a fully developed case of putrid fever will make its appearance, a disease of the gravest character, but which may be recovered from.

One of the conclusions which have been arrived at by the medical profession is that those who live in badly ventilated or drained houses are, with perhaps some exceptions depending on the effects of temperature which are not yet well understood, constantly in a condition which renders them liable to a diphtheritic attack of varying importance. It is true that there are physicians who do not like to pronounce certain cases of sore throat as diphtheritic, unless they have more or less of an alarming character, or appear during an undoubted epidemic, but diphtheria is so treacherous a disease that it is not well to strive to balance arguments at the risk of life, especially when observation has almost surely decided the question on the safe side. It is well known that persons are not as likely to take a "cold" on our Pacific coast or in some of our western territories, as in the Mississippi valley, or between it and the Atlantic ocean. It is therefore probable that organic matter has much to do with the development of "colds;" undoubtedly it has with that of influenza. If we call this organic matter zymotic, then we may assume that with the aid of the vitality of the system it works itself out, or recovery takes place without recourse to medicine. Now, in regard to the septic germs of diphtheria, it is known that they are generally present in the effluvia of cess-pools, sewers, and filthy habitations, perhaps more especially developed or active in the temperate and moist weather of spring and autumn, and mild winters. Therefore, it is reasonable to believe that persons inhabiting badly drained localities, where putrescent effluvia more or less pollute the air, never have inflammatory affections of the mucous membrane of the mouth or fauces, without having it more or less modified by this circumstance. All persons, therefore, who live in houses where the drain-pipes are not properly trapped, and where there is more or less intrusion of sewer gas through the wash-basins, bathtubs, etc., will have reason to suspect that when they have febrile symptoms, alternating with chills, but unlike those of fever and ague, and a feeling of weariness, whether accompanied with pain in the throat, or not, there may be diphtheritic complications. The above symptoms are those of milder cases. The attack, when acute, frequently commences with a decided chill, followed by a high fever. The chill and the fever are characteristic, and generally easy to be recognized by the experienced physician. The pulse, however, affords a still stronger indication, and when taken in connection with the chill and the following fever, and the condition of the throat, together with the surrounding sanitary conditions, is quite diagnostic. It is variable, and soft and weak; sometimes quite full, but easily compressible; sometimes not more frequent than in health, but generally ranging from 100 to 140 beats per minute; sometimes reaching 160, and in children going still higher. The cheeks are often of a bright red color, one cheek often much redder than the other, the latter sometimes being quite pale. There is a fluctuation in the circulation, and also, apparently, a fluctuation in the nervous force of the system. It must not be supposed that the throat affection, even when serious, will be indicated by pain, for there is often found considerable mischief, upon inspection, where the patient suspected nothing of the kind. There may be pain only on swallowing; while on the other hand there may be diminution of sensitiveness, especially in grave cases, when also the muscles of deglutition may be so paralyzed as to interfere with swallowing, and in extreme cases there may be paralysis of different parts of the body, generally affecting one side more than the other; but this condition, caused by the great development and accumulation of poisonous matter, may be relieved by the prompt administration of proper remedies. The disease is, indeed, singular in some respects. Although sometimes perfectly unmanageable, and causing death in a few hours, it is at times, even when violent, easily overcome, if attacked with resolution and courage. The paralysis which sometimes occurs at the commencement of the disease must not be confounded with that which often comes on during convalescence after serious attacks. The breath is always more or less fetid, and in severe cases is very offensive. Sometimes the membranous exudation is extensive, spreading over a considerable portion of the fauces, often causing sloughing, especially when efficient remedies are not employed. The exudation may not be confined to the throat or any part of the air passages, but may form on the mucous membrane of the intestines, and has been recognized in the evacuations of the rectum. It may also form on the mucous membrane of the larynx or wind-pipe, or even pass into the bronchial tubes, and when diphtheritic sputa has been thrown upon the mucous membrane of the eyelids, exudations have developed there. Observation has shown that the range of temperature in the axilla is lower than

in other acute diseases. There is usually loss of appetite, with vomiting, and often diarrhea; the latter are unfavorable symptoms. There is more or less delirium in all severe cases, and unless good treatment is speedily adopted the throat is liable to become gangrenous. There is great variableness, no doubt, in the virulence of the poison during different epidemics, and sometimes three fourths of the members of a family will die. The urine, in a majority of cases, at some time during the attack contains albumen, and the symptom is regarded as unfavorable, yet a majority of such cases recover. The neck is often considerably swollen, with considerable inability to move the jaws or to swallow. The tongue and throat are covered with a thickened mucus; the tonsils are generally considerably swollen when the first examination is made, and may have patches of a grayish or yellowish membrane upon them. The membrane, however, is sometimes not seen, either upon the tonsils or other parts of the mouth or throat, till the second day. The tonsils generally increase in size, and sometimes close the entrance to the wind-pipe, and render swallowing very difficult. The color of the parts is also peculiar; indeed, many of the symptoms of D. are peculiarly characteristic, usually making the diagnosis, especially when the history of the person is taken into consideration, easy.

It ought to be more generally known that D. is a disease in which relief must be expected from the use of medicines. It is septic, progressive, and cumulative; and when the system has been fully charged with its germs, it is likely to go to a fatal termination, the functions of the body seemingly participating in furnishing material for the spread of the disorder. The enemy must be repelled by such weapons as are deadly to disease germs. Disinfectants should be freely used, and medicines which keep up the animal strength. A generous diet of easily digested food, such as beef-tea, milk-punch, eggs and wine, boiled rice, and as a beverage, rice-water, with tender beefsteak as soon as the stomach will bear solid food, should be combined with such medicines as quinine and the tincture of chloride of iron. There is great waste of alkaline material in the blood in these cases, and this should be restored by the judicious administration of alkaline carbonates and chlorates. The amount of alcoholic stimulants required is variable; sometimes small quantities only are needed, but frequently they are required to combat the wonderfully depressing influence of the poison, their remedial action being similar to that which they have in cases of bites of poisonous reptiles. It is fortunate that in nearly every case the membranous exudation takes place above the larynx, or in that part of the throat which can be reached by a gargle or a sponge probang. This allows of the application of antiseptics, and no better one can be employed than a solution of carbolic acid, in the proportion of a dram, or a dram and a half, of the pure acid to a quart of water. This should be used as a gargle frequently, every half-hour, hour, or two hours. In young children who cannot gargle, a solution of rather greater strength may be applied with the sponge probang. This will in most cases relieve the local symptoms and cause the disappearance of the exudation in a few days, if the general treatment be judicious. A saturated solution of chlorate of potash may often be employed as a gargle in mild and chronic cases, but will not at all meet the demands of a severe case. What is known as chloride of soda, sold in the shops as Labarraque's disinfecting liquid, when properly diluted forms a good topical application, and before the introduction of carbolic acid, was used with great success, and is still employed by many physicians. The mischievous practice of destroying the exudation, and of course, to some extent, the tissue immediately beneath, with caustic, was in vogue some fifteen or twenty years ago, and the mortality which resulted from this practice was frightful. The application produced a wound in which the disease germs seemed to propagate themselves and enter the system, for the wound, under the circumstances, would not heal or form a protecting plastic membrane such as is developed in the presence of healthy pus. The use of chloride of lime in the sick-room, notwithstanding the denials which have been made of its virtues, has a powerful effect in destroying disease germs, and, as has been shown by experience, will render an apartment occupied by a diphtheritic patient comparatively innocuous, so that he may be nursed assiduously with but little danger to his attendants, especially if they use disinfecting gargles, and give all proper attention to cleanliness.

**DIPH'THONG** (Gr. having a double sound) means two vowel sounds following one another so closely as to form but one syllable, as in *out*. In this combination the sound is really composed of an *a* as heard in *father*, and a *u* as heard in *put*. Many double vowels in English are not real diphthongs, there being only one sound heard. The spelling of the English language has little or no relation to the pronunciation in this matter. In many syllables written with two vowels, only one sound is heard, as in *bread*. The single vowel letters, again, often have a diphthongal sound; thus, the long sound, as it is called, of *i* is really composed of the sound of *a*, as heard in *father*, and that of *e*, in *me*; and *tune* is pronounced as if written *teun* or rather *tyun*. Such words as *bread*, *field*, which are now monophthongs, were doubtless at one time real diphthongs, and are still so pronounced in many parts of England.

**DIPLACANTHUS**, a genus of fossil ganoid fishes, peculiar to the old red sandstone, in which six species have been found. The body was covered with very small scales, and the tail was heterocercal. There were two dorsal fins, which with each of the other fins were furnished with a strong spine in front, the base of which was simply imbedded in the flesh, as in the dog-fish, and not articulated, as in the siluroids. The head was large, and the mouth wide, and open obliquely.

**DIPLOGRAP'SUS**, a genus of fossil zoophytes, differing from the graptolite (q.v.) in having a double series of cells. They are found in great abundance in the anthracitic shales of the Silurian measures.

**DIPLO'MA** (Gr. *diplōō*, I double, or fold). This term originated in the ancient custom of writing solemn documents on two tablets of wax, which were doubled, or laid one upon the other (see **DIPRYCH**), or on writing material which was folded. The Roman emperors were in the habit of giving diplomas to public servants, and to couriers, to enable them to procure the use of the public servants and horses; hence diploma came to signify a royal charter or prince's letters-patent. The term is now mostly applied to instruments given by universities and other learned societies, in proof of the holder having attained a certain degree; or to the licenses held by professional persons to practice their art.

**DIPLO'MACY**, the art of managing the intercourse and adjusting the relations of foreign states, by means of ambassadors, envoys extraordinary, consuls, etc. The principles and rules of D. are embodied partly in those international customs and usages which constitute what may be called common, and in those treaties which may be regarded as statute international law. The diplomatic relations of this country are practically under the superintendence of the secretary of state for foreign affairs, but the power of sending ambassadors to, and receiving ambassadors from, foreign states, is an alienable privilege of the crown. It was doubted whether an exception had not been made in the case of Rome, by the statutes passed against papal encroachments; and it was thought expedient to remove such doubt by 11 and 12 Vict. c. 108, which authorizes her majesty to enter into diplomatic relations, provided that no person in holy orders in the church of Rome, or Jesuit, or member of any other religious order, community, or society of that church, bound by monastic or religious vows, shall be received as ambassador at the court of London. Ambassadors are not subject to the municipal laws of the states in which they reside, the theory being that they represent the persons of their respective masters, who cannot be subject to any other laws than those of their own country. If an ambassador offends against the municipal law, or abuses his character, he may be sent home, and accused before his master. Though there was much doubt on the point, this rule seems to extend to crimes against natural law, e.g., to murder, or *mala in se*, as well as to crimes artificially created by the policy of the particular state, *mala prohibita*; and it is now said that the case of Don Pantaleon Sa, the brother and secretary of the Portuguese ambassador, who was executed for an atrocious murder during the protectorate of Cromwell in 1654, was no exception, as he was not "joined with his brother in the same commission." See **AMBASSADOR**, **EMBASSY**. The arrangement of international ceremonies belongs to the subject of diplomacy. To treat it in detail would lead us far beyond our limits, and we must content ourselves with remarking a few of the customary and conventional modifications which affect the general principle of international law by which all independent states are held to be equal.

*Royal honors* are enjoyed by the empires and kingdoms of Europe, including the Swiss confederation, the grand duchies of Germany, and, amongst Catholic states, by the pope; and the same right extends to the United States of America. These, along with other rights of greater importance, include the right of taking precedence of the others in all international ceremonials. Amongst those who enjoy royal honors, the order of precedence, after much discussion, was left by the congress of Vienna on the ancient footing of custom merely. The rule thus fixed is said to be the following: Monarchs enjoying royal honors, but not crowned heads, yield precedence to those who are, whilst they enjoy it over all other monarchs, demi-sovereigns, and rulers of dependent states. This rule leaves the relative rank of the crowned heads and other classes amongst themselves undetermined, and a curious expedient has been found for obviating the necessity of a minutest classification. By what is called the *alternat*, the rank and places of the various powers are changed from time to time in a certain order determined by lot. If there are several parties to a treaty, for example, a corresponding number of copies is made of it, the name of each state being named first in the copy which it preserves, and the others in the order determined by the *alternat*. But the right to alternation has sometimes been a subject of contention. In 1742 it was refused to Prussia by Great Britain; and Hungary and Sardinia had great difficulty in obtaining it at the peace of Aix-la-Chapelle.

The subject of maritime ceremonies will be treated under its respective heads. They consist of salutes either with cannon, or with the flag or pendant, by furling it, lowering it, or pulling it down. There is also a salute with sails, which generally consists in lowering the foretopsail. Maritime ceremonials are usually made the subject of express compact, but, as a general rule, on the open seas, a ship carrying a pendant salutes a ship of a friendly power carrying an admiral, and detached ships generally salute fleets. It is provided by 22 and 23 Vict. c. 5, repealing in so far 6 Anne. c. 7, that pensions granted for diplomatic services, according to the provisions of 2 and 3 Will. IV. c. 116, shall not disqualify the holder from being elected, or sitting, or voting as a member of the house of commons.

**DIPLO'MACY** (*ante*), the science which deals with the relations and interests of nations in respect to one another. Diplomatic agents are of the following grades:

Ambassadors, ministers plenipotentiary, charges d'affaires, envoys, and consuls. In the United States, these agents are appointed by the president, with the advice and consent of the senate. If a vacancy occurs while the senate is not in session, the agent may enter upon his duties upon the appointment of the president, subject, however, to confirmation or rejection by the senate at a future time. In practice, the secretary of state, under the direction of the president, takes charge of the diplomatic relations of the government, giving to the agents their instructions and keeping himself in close correspondence with them. In great emergencies it is not unusual for nations to appoint special commissioners to settle a special difficulty, or to draft a particular treaty. In the United States, the necessity and utility of keeping ministers residing at foreign courts has sometimes been questioned; but the practice is continued in the belief that it is favorable to peace between nations by affording facilities for prompt explanations of disputes as they may arise, and also because it is thought that American citizens traveling or residing in foreign countries often need such protection or advice as only a minister or consul is qualified to give. There can be no doubt that diplomatic intercourse, regularly established and maintained, begets between nations sentiments of mutual respect and forbearance, and tends to keep alive that feeling of universal brotherhood which is the richest and ripest fruit of a Christian civilization. It is the duty of a foreign minister to study the institutions, habits, and even prejudices of the nation to which he is accredited, and to keep his own government advised of every movement affecting its peace and welfare. It is also his duty to convey information to foreigners in respect to the government and people of the nation which he represents, in order to abate or remove national prejudices and awaken fraternal feelings. Of late years, American consuls have done the country a valuable service by gathering information as to the productions, manufactures, and trade of foreign nations, and finding new markets for the products of American industry.

**DIPLOMATICS**, the science of ancient writings. The term can scarcely be said to have been at any time in general use in this country, and even on the continent it has latterly given way to the more convenient and descriptive term, paleography (q.v.).

**DIPLOP TERUS**, a genus of fossil ganoid fishes, four species of which have been discovered in the old red sandstone, and two in the carboniferous series. They have heterocercal tails, with double anal and dorsal fins, opposite each other, but having the dorsal pair a little apart. The head is large and flattened, and the teeth are fewer and larger than in the allied genera. The scales are perforated with small foramina.

**DIPPEL'S ANIMAL OIL**, called also empyreumatic animal oil, or rectified oil of hartshorn, is prepared by the destructive distillation of bones in close vessels, when bone-black (q.v.) is left in the retort or vessel, and the crude oil distills over into a suitable receiver. When obtained in this manner, it is a thick viscid oil of a brown color, and a very disagreeable odor, but on redistillation it may be obtained limpid and colorless. Air and light affect the pure or rectified oil, and render it colored and somewhat viscid. Its elementary constituents are carbon, hydrogen, nitrogen, and oxygen, and it contains a number of volatile organic bases, such as aniline, picoline, etc. D. A. O. is a powerful medicinal agent, and when swallowed in doses of a few drops, it is antispasmodic, and stimulates the vascular and nervous systems. In large doses, it is a powerful irritant poison.

**DIPPER**, *Cinclus*, a genus of birds of the thrush family (*merulidæ*), distinguished from the other birds of that family by an almost straight, compressed, sharp-pointed bill, and still more by their manners and habits. They frequent clear pebbly streams and lakes, feeding chiefly on mollusks and on aquatic insects and their larvæ, which they seek even under water, diving with great facility, and moving about for a short time at the bottom of the water. They carry their rather short tail elevated after the manner of wrens, which they also resemble in their "frequent becks" or dipping of the head, accompanied with an upward jerking of the tail. One species is found in Britain, the COMMON D., or WATER OUSEL (*C. aquaticus*), a bird rather smaller than any of the British thrushes, of a generally dark-brown color, with throat and upper part of the breast pure white. It is found throughout the whole of Europe and the n. of Asia, but chiefly in hilly or mountainous districts. It is not gregarious. The D. never fails to attract notice, as it sits upon some stone in the midst of or beside the stream, its white breast rendering it conspicuous as it repeats the movement from which it derives its name. It builds a very curious nest of interwoven moss, domed and with the entrance in the side, usually in some mossy bank close by a stream, and often near or under a cascade. The assertion which has been made, that the D. walks without apparent muscular effort at the bottom of the water, is incorrect; its feet are not well formed for walking, and it moves under water by means of its wings—which are short—not without much muscular effort. The statement also often made, that it eats the spawn of salmon and other fishes, in the belief of which it is much persecuted in Scotland, has never been sufficiently authenticated. Other species of D. are found in Asia and North America. In Scotland, the D. is called the water crow.

**DIPPING-NEEDLE**. If a magnetic needle be supported so as to be free to move vertically, it does not at most places on the earth's surface rest in a horizontal position, but inclines more or less from it. If the vertical plane in which the needle moves is the magnetic meridian of the place, the angle between the needle and the horizontal line is

called the dip or inclination of the needle. The dip of the magnetic needle at any place can be ascertained with very great exactness by means of the dipping-needle. It consists of a graduated circle fixed vertically in a frame, and moving with it and a vernier on a horizontal graduated circle. This last is supported by a tripod furnished with leveling screws. At the center of the vertical circle, there are two knife-edges of agate, supported by the frame, and parallel to the plane of the circle. The needle rests on these knife-edges by means of two fine polished cylinders of steel, which are placed accurately at the center of the needle, and project at right angles from it: so adjusted, the needle moves with little or no friction. It is so made, moreover, that before being magnetized it remains indifferently in any position; after magnetization, therefore, the dip which it shows is wholly due to the magnetic influence of the earth.

In order to understand how an observation is made with the dipping-needle, we must regard the directing force of the earth's magnetism exerted upon the poles of the needle in any vertical plane in which it may happen to be, as resolved into two forces, one acting at right angles to the plane, and the other acting in the plane. There being a corresponding but opposite force at each pole, we have thus two statical couples acting on the needle—one tending to turn it at right angles to the plane in which it moves, and the other tending to bring it round to a position in the plane such that the needle and the forces of the couple may be in a line. In the dipping-needle, the mode of support completely neutralizes the first of the couples; and the position that the needle takes in any plane is due wholly to the second. When the plane of the needle is at right angles to the magnetic meridian, the forces of this latter couple act vertically, and bring the needle to the same position. This, then, gives us the means of determining the magnetic meridian, for we have only to bring the vertical circle round till the needle stands at 90° to put it in a plane at right angles to that meridian; and then by moving the vernier on the horizontal circle over 90°, we place the upper circle and needle in the plane of the magnetic meridian. The dipping-needle thus serves the purpose of a declination needle (q.v.). In bringing the needle round from the plane at right angles to the magnetic meridian, the dip is less and less, till it becomes least in the plane of that meridian. We might thus also find the magnetic meridian, for it is that plane in which the dip of the needle is least. When the needle is in the plane of the magnetic meridian, the couple which acts in other vertical planes at right angles to them disappears, and the whole force of the terrestrial magnetism acts at each pole of the needle, forming a couple which swings the needle round till it stands in a line with itself. The degree on the circle then pointed to by the needle is the dip at the place of observation. Two readings are necessary, for the reason stated in the DECLINATION NEEDLE. One reading is taken, the needle is then reversed so as to change its supports, and then a second reading is noted, and the mean of the two gives the correct reading. The position of the needle when the dip is read off is manifestly the same that a needle suspended in air, if that were possible, and free to move in any way, would finally assume. In resolving, therefore, the total directive force of the earth as we have done above, we must keep in mind that it always acts parallel to the direction of the dipping-needle.

#### DIPSACEÆ AND DIPSACUS. See TEASEL.

**DIPSAS** (Gr. a kind of serpent), a genus of non-venomous serpents of the family *colubridæ*, of very elongated form, and with a thick, broad, and obtuse head. They are tree-snakes, inhabitants chiefly of the warm parts of Asia and America. One species only, *D. fallax*, somewhat doubtfully referred to this genus, occurs in the s. of Europe. Some of the species are of great size. A large and beautiful species is found in Java and Sumatra. The form is more attenuated than in others of the genus.

**DIPSOMANIA**, or **ONOMANIA**, from the Greek words *dipsa*, thirst, or *oinos*, wine, and *mania*—terms of modern invention, to denote an irresistible or insane craving for alcoholic stimulants, when occurring in a habitual or confirmed form, and requiring confinement or restraint of the person for its cure. Much discussion has taken place in regard to this and other forms of what is often called moral insanity; the most recent views of physicians, however, tend to show that the drinking insanity, or *furor bibendi*, as it was called by an early writer on the subject, is often associated with other forms of mental derangement, and is very apt to be, in connection with one or more of these forms, hereditarily transmitted, even through several generations; so that the really physical or insane character of the craving for stimulants, at least in some cases, may be regarded as a well-established fact in medicine. For the legal and general questions in connection with this subject, see **INSANITY** and **INTOXICATION**.

**DIPSOMANIA** (Gr. *dipsa*, thirst, and *mania*, madness, or eager desire) is a term intended, whether correctly or not, to denote a condition in which certain individuals manifest an irresistible craving for alcoholic drinks. **ONOMANIA** (Gr. *oinos*, wine), used by German writers; and the English **DRINKING INSANITY**, are also intended to designate the same state. It is of importance to distinguish dipsomaniacs from ordinarily intemperate and drunken individuals. In our streets and in society, we are only too familiar with the various phases of the habit and vice of drunkenness, and the different grades and circumstances of drinkers, such as the morning dram-drinker; the jolly social drinker; and the individual who, knowingly and intentionally, gives himself up to a debauch. While many thus of their own choice degrade and injure themselves, they are

generally able, for a time at least, to perform tolerably well their usual occupations during business hours. Many hard drinkers can exercise wonderful control over themselves, choosing the time to drink and the time to keep sober; and while sober, can discharge all their family, professional, social, or even religious duties—so far at least as outward appearances go. Some of them may drink continuously, until attacked by what is called *delirium tremens* (q. v.), or fall into the state of *delirium ebriosum* (q. v.), or what has been called *mania a potu*; but when the supplies are stopped, and the necessary treatment is undergone, they are soon able to resume their usual duties, and too soon, in general, their former practices.

There is, however, especially in persons of a nervous and sanguine temperament and constitution—and more readily in women than in men—a condition in which the mere vice is transformed into a disease, the vicious habit into an insane, impulsive propensity, and then the drunkard becomes a dipsomaniac. The alcoholic principle, by habitual abuse, perverts the action, if not the nutrition, of cerebral matter; and the frequent disturbances of the mental functions from fits of intoxication, the loose and irregular habits engendered, and the alternate states of remorse and attempts to drown conscience by more copious libations, all combine to create the dipsomaniac. He loses entire command over his will; has no power to resist the craving for alcoholic stimuli; and is transformed into the involuntary slave of an insane propensity. Physically, the dipsomaniac has a lamentably broken-down aspect; limbs feeble and tremulous; visage pale, leaden-colored, or sordid; and eyes watery and lusterless. But in the manifestations of mind and heart, the change is still more sad. A process of mental deterioration goes on simultaneously with the habit of indulgence; the main aim of life is how to obtain liquor; capacity for business is limited to the means of gratifying the craving; the precepts of morality and religion, the ties of nearest and dearest kin, have no sway over him; indeed, no consideration, human or divine, will interpose any barrier in the way of gratifying the propensity, whenever it is possible. Nor does he now drink with real relish, socially and convivially, but will swallow spirits, away from society and observation, even as it were a drug; and the only satisfaction derived from the act is, that it secures insensibility to the wretched state of mind which prompts the insatiable desire. When this has gone on for some time, although a suspension of the use of stimulants be imposed by the interference of friends, or the occurrence of an attack either of the form of delirium or maniacal excitement mentioned, yet his mind has suffered so materially, that unless control is exercised over him, and continued for a considerable period, he returns immediately like the “dog to his vomit.” His moral feelings become more and more perverted, and his intellectual powers weakened. He is thus rendered either facile or wasteful, and incapacitated for the ordinary business of life; or he is irascible, resentful, or mischievous, and torments and annoys those about him, or commits homicide or suicide; or he becomes decidedly insane. Such is acquired dipsomania. But very frequently it is met with as a disease, *ab origine*—a constitutional, and, in the greater proportion of instances, a hereditary affection. When it takes this character, D. resembles other constitutional diseases; and such cases especially illustrate its affinity to insanity. It is well known that gout and rheumatism, or disease of the heart, may be developed from errors in the mode of living of individuals in whose family connections there is no sign of predisposition; while, on the other hand, these diseases may also exist in virtue of a strong hereditary tendency, without any appreciable infringements of the laws of health. And so also D.; for, while frequently resulting from acquired vicious habit, it occurs likewise from an insane hereditary taint, very frequently visited on children by the sins of their parents, especially if the latter have suffered from repeated attacks of delirium tremens, or have been in reality confirmed dipsomaniacs. Indeed, it has even been met with in the offspring of dipsomaniacs during the years of childhood, and that also in the sudden paroxysmal form. But what goes still further to prove its affinity to insanity, is the well-known fact, that in the family of the dipsomaniac, not only several cases of this drink-craving propensity are often met with, but marked instances of mental disorder in other forms. Some interesting examples of this may be found in the *Edinburgh Medical Journal* for April, 1858, by Dr. Thompson of the Perth prisons. When D. thus occurs from constitutional organization, the disease is assuredly of a worse type than when it springs merely out of the vicious habit of drinking. There is generally more eccentricity of habit and deportment, more perversity of mind and disposition, and more untruthfulness and deceit, which is a remarkably uniform feature in this malady. The victim of it is more unscrupulous in the means employed to gratify the ruling desire of existence; and when the disease is fairly developed, and allowed to take its course unrestrainedly, the moral sense becomes utterly perverted, and the intellect annihilated, so that the affected is readily led to the commission of crimes which would not otherwise be perpetrated, or sinks into a state of complete imbecility or hopeless mania. Whether, therefore, the disease exists in its ordinary phases and intensity from voluntary intemperance; or whether it springs out of the propensity, as a consequence of abnormal organization—and these are sufficiently characteristic to present a marked line of distinction from the ordinary vice of intemperance—the pathological and mental phenomena and results are the same—viz., an insatiable craving for alcoholic stimulants, with complete loss of self-respect and self-control in gratifying the desire, despite all obligations due to God and to man. There are generally also some special features in each case, afford-

ing additional evidence of decided mental unsoundness. Some of these are wastefulness and senseless extravagance; ridiculous eccentricity of conduct; gross indecency of behavior, and obscenity and profanity of language; tendency to theft of articles of little or no value—often of one class or kind of things; extreme perverseness and vindictiveness of disposition; and impulsive violence, which leads readily to the commission of homicide or suicide.

These, then, are the features, variously combined in different cases (of which many examples could be easily given), which distinguish instances of D. from ordinary drunkenness, and warrant the opinion that the condition described is a form of mental affection—a disease, like any other insanity. Almost all medical men, we believe, now hold this view, or at least that it should be treated as an insanity; and it has of late been very widely accepted by the general public, at any rate by all, without exception, who have come in contact with instances in their own families or among their friends.

If such, then, is a correct view of the case, it follows that special physical treatment must be adopted before moral and spiritual agencies can be expected to operate with any chance of success; and as the dipsomaniac is incapable of governing his own will, and making any effort to subdue his ruling desire, it is evident that he should be placed under the power of others who have the means of controlling him. From the very nature of the malady, however, it is scarcely to be expected that the inveterate drunkard will voluntarily submit to control, or continue under it for a sufficient length of time to receive lasting benefit: and therefore it seems essential, as in the case of other insanities, that legal power, with proper precautions and restrictions, should be available, to secure the possession of his person, and the protection of his property. It is undoubtedly the duty of a good and wise government to provide for such care, when it is so well known that the consequences of unrestrained action may be so serious to the individual chiefly concerned; when families are so often thereby plunged into deep distress or absolute ruin; and when the amenity of society is so frequently outraged by a display of mischievous eccentricity, or glaring indecency, or by the occurrence of some flagrant crime. "The liberty of the subject" is a precious trust, but the absence of law to meet the case of the insane drunkard, is in reality license for evil, since no precaution is taken to prevent most grievous infringements of the liberties of others. It is certainly an overstrained delicacy in legislation to shirk interference with a class of cases which lead to so much private misery and public expenditure, as the records of our courts of law, prisons, poor-houses, and lunatic asylums can amply attest. But considering the case of the dipsomaniac from another point of view, a facility by law to control, would confer on himself an unspeakable benefit. It would thus afford him his only chance of cure and restoration to society, instead of permitting him to go on to wreck and ruin. Indeed, the neglect of law to provide such a check and remedy, seems inconsistent, unjust, and inhumane, when we consider that while it permits the insensate drunkard to endanger his life, to waste his property, and deprive his family of that which they are justly entitled to expect from his hands during life, or to fall to them at his death, it holds him responsible for any criminal act he may commit. No doubt the law assumes that he drinks voluntarily, and with his eyes open to all the consequences, and that his practices therefore form an aggravation of his guilt; but such is not the case, for he drinks—as has been shown—involuntarily, and without any reflection as to ultimate consequences; and he is manifestly unable to exercise his reason aright, or govern his will. That the existing law of lunacy does not meet the case of insane drinkers, is well known, and much felt. One would imagine that the definition of insanity—"a person so diseased and affected in mind as to render him unfit to be at large, either as regards his own personal safety and conduct, or the safety of the persons and property of others or of the public" (20 and 21 Vict. c. 71, s. 3); and again, "a person of unsound mind" (25 and 26 Vict. c. 54, s. 1)—recognizes a dipsomaniac as a fit object for control. But the ancient dicta of English and Scotch judges, as to the nature of insanity, still appear to adhere to the legal mind; and as medical certifiers now require to state the facts on which they form their opinion, the statement that one or the chief manifestation is excessive intemperance, or an uncontrollable craving for intoxicating liquors, is quite enough to prevent a sheriff—or at least some sheriffs—from granting the wished-for warrant. He declines to interfere unless there is evidence of some furiosity in the case, or the existence of a delusion; and in all probability, were he to do otherwise, and the case be carried into court, a deliverance would be given against the plea of insanity. At any rate, the uncertainty in the administration of law in such cases, and the danger of subjection to annoyance and expense, even did they gain their plea, deter medical men from granting certificates, which, otherwise, they would most unhesitatingly do. In the last lunacy amendment act (29 and 30 Vict. c. 51, s. 15, 1866), as permission is given to the superintendent of any asylum, with assent, in writing, from one of the commissioners in lunacy, to admit as a boarder any person wishing to submit himself to treatment—whose mental condition is not such as to warrant certificates of insanity—it was supposed likely to open a door for the admission of dipsomaniacs. But it has only in a very few instances, and for a very brief period of time, been taken advantage of, under the temporary pressure brought to bear on them by friends, etc. Indeed, there is the same difficulty in getting individuals to go voluntarily into private sanatoria, refuges, and boarding-houses for inebriates—where no legal steps are available—or, when admitted, to detain them sufficiently long so as to effect a cure.

Establishments for inebriates, on a small scale, have existed in this country for many years; and there are at present several excellent ones, for the middle and upper classes, in various parts of the country, particularly in the counties of Argyle, Ross, Inverness, Forfar, and Perth; besides, several medical men, clergymen, and farmers throughout Scotland receive one or two boarders of this class. Into these places, however, only a very few individuals go quite voluntarily: in fact, it is generally under more or less constraint. Straited circumstances, bodily suffering, the tears and entreaties of relations, threatenings of being cast off altogether, and such-like influences, may succeed perhaps in one out of ten or twelve instances; but abstinence from drink, judicious medical treatment, good diet, pure air, exercise, occupation, and amusement, so improve the physical condition, that ere-long, and before deeper and more radical changes can be effected, or the tone of the moral feelings restored, they become restless, and demand liberty as a right, which they know well cannot be disputed. Out in a few weeks or months, therefore, fully three fourths of those admitted go, or are taken by injudicious or timid friends, and the result may easily be imagined. Years rather than months of control, and gradual trials of liberty on probation, are necessary to effect a permanent cure in any considerable proportion of the more confirmed cases of this malady. Taking into consideration, therefore, these uncertainties, there is evidently not much inducement for parties to invest money in the establishment of a desirable and trustworthy institution. For a good building, in a pleasant and salubrious situation, with some ground attached, must be secured; the furnishings must be comfortable, the cooking good, and considerable opportunities must be provided for within-door and out-door occupation, amusement, and cheeriness. In fact, all the arrangements must be made so as to provide such new and relishable enjoyments as will counteract or take the place of the cravings for alcoholic stimuli, and prevent, as much as possible, discontentment with the situation in which they are placed. Admission to such private boarding-houses is generally at the rate of £100 per annum. The chief stipulations made on entrance are, that no pocket-money be allowed; that no stimulants are to be given, unless under medical direction; and that intimation be made at all hotels, taverns, or spirit-shops in the locality, that no debts will be paid for drink furnished to the boarders. The only public institution in Great Britain for the treatment of inebriates is the Queensberry lodge, Edinburgh, in connection with the house of refuge. It is a handsome building, erected some years ago, and comfortably furnished so as to accommodate 27 female boarders of the better classes, at the rates of from £40 to £100 per annum. Already a considerable number have been admitted; and in several instances apparently with excellent results, notwithstanding the difficulty experienced in the most of cases in detaining boarders a sufficient time.

In several cities of the United States of America, and as far back as 20 years, somewhat similar institutions are in active operation, some of them amply endowed, others partly supported from public funds, although into all the admissions are mostly voluntary. Of these there are now upwards of 12 homes or retreats; and the Boston "Washingtonian home," is pointed to as a model institution. But the institution about which we have heard most is the New York state inebriate asylum, at Binghamton. It is a massive and costly structure, sufficient to accommodate about 200 individuals, amply state endowed and possessing every arrangement and appliance for the treatment of the unfortunate class requiring its aid. Here an average of 40 per cent of the cases admitted are said to have been cured. It is evident, however, from the number of boarders reported as annually undergoing treatment in these various American retreats, that they receive all sorts of drunkards; and we fear that the good accomplished must, in a large proportion of instances, be only partial and temporary. Thus, in the Washingtonian home, which—according to one of its reports—has accommodated an average of about 18 persons daily, and is said to have had from 250 to 300 cases annually under treatment, the necessarily brief average residence of each holds out little hope that much lasting benefit can have resulted in cases at least of such confirmed inebriates as we have described under the name of dipsomaniacs, and for whom legislation is desirable. It is supposed, however, in America, that these state-supported institutions have been economical by keeping inebriates out of the alms-houses, etc., and in restoring about one third of bread-winners to honorable citizenship, and thus preventing them and their families from falling as a burden on the state. In 1870, an "association for the cure of inebriates" was formed, composed of physicians, superintendents, and friends of inebriate asylums, which has ever since been most active in its operations, and done much by meetings, publications of transactions, and otherwise, to help forward the philanthropic movement, and in every particular on the lines of this paper.

The Americans are in advance of us in legislation regarding the care of the person and property of inebriates; for to the magistrate, or rather judge, is committed the care and custody of all insane persons, and of all persons who are wasteful and incapable of conducting their own affairs, in consequence of habitual drunkenness; and he is empowered to provide out of their estates for their safe keeping and maintenance, and for the maintenance of their families and the education of their children. Hence, it might be inferred that legal power might enforce the care and treatment of insane drinkers in lunatic asylums, or in reformatory asylums, such as those at Binghamton or Boston. Yet such powers are not often called into effect, doubtless from the knowledge that such exists, and that the best course is to submit voluntarily and prevent further proceedings.

Freedom of legislation is more natural in a new country, where antiquated precedents and prejudices do not drag the wheels of reform, and where common-sense views of social interests prevail. Accordingly, in southern Australia a great step was taken in the right direction, chiefly through the exertions of Dr. M'Arthy, of Melbourne, who had considered with lively interest the discussions which took place in this country regarding the treatment of dipsomaniacs, after the publication of papers on D. by Dr. Peddie in 1858 and 1860, and a lecture by sir Robert Christison in 1861. In 1867, after a full ventilation of the question, the government carried a measure placing inveterate inebriates in the same category with insane persons, and providing for them in connection with a lunacy amendment act. But this was soon found to be a mistake, and accordingly in 1873 "an act" was passed "to provide for the treatment and cure of inebriates." The government did nothing in the way of grants towards this object; but the Melbourne retreat, founded for upper-class boarders, notwithstanding financial difficulties at first, is now doing good work.

In Scotland, a conviction has long since been felt that some law was absolutely necessary to meet the cure of insane drinkers; and in 1857 and 1861, the commissioners in lunacy gave utterance to most decided views to that effect. Some with them have thought that provisions of this kind should be embodied in a lunacy act. But there is good ground for holding that the case requires special legislation; and that separate asylums, sanatoria, reformatories, or by whatever name inebriate institutions may be called, should be provided and licensed for this class of the unsound in mind. Interference with personal liberty would thus be more in accordance with the delicacies of the case, less painful to the feelings of those chiefly concerned, and more likely to secure the humane and remedial objects contemplated. Besides, the arrangements proposed would greatly relieve ordinary asylums, and apart from this, the malady itself could in many respects be much better treated when separated from other insanities.

Were sufficient facilities afforded, under government sanction, for the control of dipsomaniacs, and their detention until fit for liberation, there is no doubt numerous institutions—and better than those hitherto existing on voluntary enterprise—would spring up in various parts of the country, to accommodate individuals of all grades of society. Institutions so licensed, and endowed with necessary powers, would not only be productive of much public good, but be remunerative. Even supposing it necessary that government should establish three or four inebriate asylums in central situations of the country, these would soon be found to a great extent to be self-supporting, while they would assuredly lessen the burdens of the country otherwise, by the diminution of disease, destitution, and crime. Parochial boards, too, might send their inveterate drunkards into such asylums with more benefit and more economy than they can keep them in the wards of a workhouse.

To remove objections, two points must be attended to. The first is, that careful inspection of the proposed institutions be made by commissioners appointed for the purpose, so as to secure that all necessary humane and remedial arrangements be properly carried out, and no one detained longer than is essential for recovery; and the second is, that they, along with the medical superintendents, should decide when inmates, although still under control, are sufficiently sane to execute any testamentary deeds, or to conduct other business matters, or to perform—under more or less surveillance, of course—any external civil privilege; or when they may be allowed probational leave of absence, as a preliminary step to final liberation.

In 1870, Mr. Dalrymple, M.P., took up the foregoing views warmly, and in the following year introduced his first bill. On the second reading a select committee was appointed to inquire into the whole subject; and a great mass of testimony borne by magistrates, governors of prisons, medical men, superintendents of lunatic asylums, and of inebriate asylums in America, was taken, and has been given at full length in the blue-books.

In the following session, Mr. Dalrymple brought in his second bill, founded on the report of the aforementioned committee, which strongly recommended the adoption of certain legal provisions of a mixed reformatory and punitive character; but the death of Mr. Dalrymple shortly afterwards arrested the further prosecution of any measure on this subject before parliament. However, a subject of so much importance and general interest was not likely to be altogether pushed aside and forgotten; and accordingly it was revived and warmly agitated in 1874-75 by various branch associations of the British medical associations; and a further impulse given to it by the paper read by Dr. Peddie at its meeting in Aug., 1875, and the discussion which followed. The practical result was the formation in London of a "Society for Promoting Legislation for the Control and Cure of Habitual Drunkards," with lord Shaftesbury as president, and a long list of church dignitaries, members of parliament, and others as vice-presidents and other office-bearers. The society set at once to work to frame a bill on the basis of the select committee's report; and Dr. Cameron, M.P., took charge of it, but too late for the second reading. A new bill was thereafter drawn and introduced in 1879 by lord Shaftesbury in the house of lords and Dr. Cameron in the house of commons, through both of which it had an easy passage. This is not difficult to understand, as its provisions are so mild, and its character so different from that desired by those who had given most attention to the subject, that it was not thought worth any active opposition. The emasculation of the select committee's report, of Mr. Dalrymple's bills, and Dr. Cameron's first bill,

may be at once understood, when it is mentioned that the mental phase of habitual drunkenness is kept in the background; that the existence of retreats is merely sanctioned, but when erected, to be regulated and inspected, and that admission is never to be compulsory, but only permissive, although some power of detention is given. No wonder that the last report of the society mildly says: "The 'Habitual Drunkards' act,' as passed, does not quite come up to the expectation of your committee, but they congratulate all interested in the reformation of the inebriate on the affirmation by parliament of the principles on which the act is based;" and again: "Your committee have every confidence that, provided only adequate opportunity be afforded, many confirmed drunkards will gladly avail themselves of the power of isolation for a time from the many temptations by which they are at present surrounded."

It was fixed that this act should come into force on 1st Jan., 1880, and it is to be hoped that it may prove more wide in its operation and more effective than can at present be fairly anticipated; for the existence of a compulsory clause is essential to the working of the voluntary clause, and would have led to arrangements for reformatories for the habitual drunkards of our police courts and prisons, and not confined the operation of the act simply to the better classes of society.

**DIPTERA** (Gr. two-winged), an order of insects, which received from Aristotle the name it still bears. Its distinguishing characters are so obvious that it has been acknowledged, with little change of its limits, by almost all naturalists. *FLY* is a popular name very generally applied to dipterous insects, and often with some distinguishing prefix (as house-fly, flesh-fly, blow-fly, bot-fly, crane-fly, etc.), although it is sometimes used with such prefix to designate insects not belonging to this order (dragon-fly, day-fly, May-fly, etc.). Midges, gnats, and mosquitoes are also dipterous insects. In the number of species which it contains, this is one of the most extensive orders of insects: some of the species are also remarkable for the immense multitudes in which they appear; and although most of them are of small size, and few attract us by brilliant hues, not a few are important on account of the annoyance or mischief which they cause, either in their perfect or in their larva state; whilst many of their larvæ (maggots) are also very useful in consuming putrescent animal matter, which might otherwise prove a source of pestilence.

The *D.* have only two wings, which are membranous and simply veined. A little behind the wings are two small slender organs called *halteres*, poisers, or balancers, the use of which is not well known. They are usually present even in those exceptional insects of this order in which the wings are not developed. The head of the *D.* is generally in great part occupied by the large compound eyes, which often contain thousands of facettes; and besides these, three simple or stemmatic eyes (ocelli) are often also present, placed upon the crown of the head. The mouth is formed exclusively for suction, and is usually furnished with a short membranous suctorial proboscis, composed of parts which represent, although so differently modified, the portions of the mouth in coleopterous and other masticating insects, some of the parts, however, often disappearing. The proboscis of many is capable of piercing the skins of animals on the juices of which they feed; others are quite destitute of this power of piercing. Many feed chiefly on saccharine and other vegetable juices. In some genera, the perfect insect seems destitute of a mouth; and the term of life, after the perfect state has been attained, very brief in some, appears to be brief in all. The power which many dipterous insects possess of walking even on very smooth surfaces, in any position, even with the back downwards, familiar to every one in the example of the common house-fly, has not yet received a sufficient explanation. The opinion that their feet are furnished with disks for the formation of a vacuum, has been called in question, but nothing satisfactory has been substituted for it. The terminal rings of the abdomen in the females of many species, form an ovipositor capable of piercing the substances in which the eggs are to be laid, and composed of pieces which may be exerted or retracted into one another like those of a telescope. The eggs are very generally deposited in putrescent animal substances, but those of some kinds in the bodies of living animals, some in vegetable substances; the larvæ of some live in water; the eggs of a few are hatched within their own bodies, and the larvæ of some even remain there till they pass into the pupa state. All the *D.* undergo a complete metamorphosis. Their larvæ are destitute of true feet, although some of them have organs which serve for the same purpose; some have a distinct head; but others have the head soft and changeable in form, capable of being retracted into the body, and distinguishable only by its position, and by the organs of the mouth. Those which dwell in water or in fluid putrescent matters, have a retractile tail-like prolongation of the body, terminated by a radiated expansion, which communicates with air-tubes, and constitutes part of a very remarkable respiratory system. The larvæ of some *D.* spin cocoons when about to pass into the pupa state; but in others, the skin of the larva hardens and encases the pupa; the perfect insect making its escape by forcing off with its head the end of its pupa case.

**DIPTERA CEE**, or **DIPTEROCARPA CEE**, a natural order of exogenous plants, consisting of beautiful and majestic trees, natives of the East Indies. Some trees of this order, of which about 50 species are known, are highly valuable as timber-trees. Among them is the *Sal* (q.v.), the most esteemed timber-tree of India. They abound also in balsamic resin, and their resinous products are used for a variety of purposes. See:

ANIME, CAMPHOR, COPAL, DAMMAR, VARNISH TREE, and SAL.—*Dipterocarpus*, the genus from which the above order has received its name, contains several species of the noblest trees of India. They abound in the warm parts of the e. coast of the bay of Bengal and the eastern peninsula. The wood is used for house-building, ship-building, etc. *D. turbinatus*, the GURJUN or GOORJUN TREE, the species by which the genus first became known, often attains a height of upwards of 200 ft., and a girth of 15 ft. It has a pale-gray trunk, rising without a branch till it forms at its summit a small symmetrical crown. The leaves are broad, glossy, and beautiful; the flowers in white racemes, but not conspicuous. The wood is hard, close-grained, and durable. A fragrant oil exudes from the trunk, which is extremely valuable for pitch and varnish, and is also used medicinally. It is procured by cutting transverse holes in the trunk, pointing downwards, and lighting fires in them, which causes the oil to flow. The tree is sometimes called the WOOD-OIL TREE. This oil or balsam is also procured from other species of *dipterocarpus*. *D. trinervis* yields a resin which is valuable for plasters, and acts on the mucous membranes like balsam of copaiva. The Javanese smear banana-leaves with this resin, which burn as torches, with a pleasant odor and white light.

**DIPTERUS**, a genus of fossil ganoid fishes, peculiar to the old red sandstone, in which two species have been found. They derive their name from their most striking characteristic—the double anal and dorsal fins, which are opposite to each other. The head is large and flattened, the teeth subequal, the scales perforated by small foramina, and the tail heterocercal.

**DIPTYCH** (Gr. *diptycha*), a double writing-tablet, or two writing-tablets, which could be folded together. Herodotus speaks of such a tablet, made of wood and covered with wax. It was in the later Roman time, however, that they were most used, and those which have been preserved belong chiefly to the period when classical was merging into mediæval life. The beautiful carving with which they are often covered on the outside, consequently represents not unfrequently a combination of classical and of Christian subjects. Ivory and metal were sometimes employed in place of wood; but the construction was always the same, the wax with the writing being in the inside. Under the emperors, diptychs were distinguished into consular and ecclesiastical. The former, which were presented by the consuls and other magistrates to their friends, and those officially connected with them, on their entrance on office, were inscribed with their names and bore their portraits. The ecclesiastical diptychs, on the other hand, are decorated with scenes from sacred history, and were preserved in the churches as part of the sacred ornaments. Those that exist are of various sizes, rarely exceeding 8 in. by 4.

**DIPUS**. See JERBOA.

**DIR'CE**, in Greek legend, the personification of a fountain (and stream) at Thebes, from the water of which Hercules derived a part of his strength, and which was usually identified with the fountain of Ares in the legend of Cadmus. Besides the fountain, there was the grove of Dirce, at which sacrifices for the dead and other rites were performed. According to the story, Dirce, the wife of Lycus, king of Thebes, had sorely persecuted Antiope, who at last escaped to Mt. Cithæron, where her twin sons, Amphion and Zethus, were being brought up by a herdsman who was unaware of their parentage. Mother and sons met, but had not recognized each other, till Dirce, who had come to a hill for a Dionysiac ceremony, proposed that Amphion and Zethus should tie Antiope to the horns of a wild bull to be dragged to death. They were about to do so, when the herdsman announced their relationship, and they then tied Dirce to the bull instead. She was dragged over the hill to the fountain into which she was transformed.

**DIRECT**. See CONSANGUINITY.

**DIRECT AND RET'ROGRADE**. In astronomy, the motion of a planet is said to be direct when the planet goes forward by its proper motion in the zodiac according to the succession or order of the signs (i.e., from w. to e.), or when it appears to do so to an observer. On the other hand, it is said to be retrograde when it appears to go the contrary way.

**DIRECTOR**, one of a number of persons appointed to conduct the affairs of joint-stock undertakings, such as banks, railways, water and gas companies, fire and life assurance companies, and various kinds of manufacturing and trading concerns. The office of a D. is in all cases one of less or more responsibility, sometimes of considerable risk, and according to commercial maxim, ought not to be accepted lightly or for the mere honor which is supposed to be incidental to the position. On this point, unfortunately, there is not a little loose morality and want of due consideration. Men are seen to enter on the office with scarcely a thought of attending to their duty, or of the injury they may inflict by allowing their names to be attached to undertakings in the management of which they cannot be said to take any particular interest. Latterly, so many instances have occurred of the perfunctory performance of the duties of directors, greatly to the damage of those who confided in them, that, perhaps, new and more wholesome views may arise on the subject. As a member of a body incorporated by the legislature, a railway D. is bound to administer the affairs of the company only with the means legitimately put at his disposal, nor can he be expected to incur any personal liability to sustain the general operations. Usually, however, when there is any tem-

porary or peculiar shortcoming in the finances, the directors overdraw to a certain extent the company's bank account on their personal responsibility; in all such cases, and where the outlay has been justifiable, the shareholders rarely decline to authorize measures which will relieve the directors of their obligations. In the case of banks, there are usually two kinds of directors—the ordinary and the extraordinary. The ordinary directors are practically the conductors of the undertaking, while the extraordinary attend only on particular occasions, and are, in fact, little else than ornamental appendages, whose names impart a degree of distinction to the concern. As regards bank as well as railway directors, it is the rule that they must respectively possess a certain amount of stock. It is an understanding that the directors of railways, banks, and assurance companies, should be paid in some way for their services. Being mostly men in business, they cannot be expected to give away their time and take trouble for nothing. Their payment, however, in the shape of an *honorarium*, is generally trifling in comparison to the amount of labor which is to be encountered. At meetings of shareholders, small sums are voted to be set aside for the directors, which sums are for the most part appropriated in the ratio of attendance. The fee of a bank D. is not usually half a guinea at each meeting; though it is as customary for those present to divide amongst them the sum set apart for the occasion, wherefore the regular attenders get most. The insignificance of these fees, even where no stinginess prevails, is employed as an argument why anything like a scrupulous examination into affairs is not reasonably to be expected—an argument seemingly of no great moral or legal force; for it is clear there can be no valid excuse for neglecting a trust which has been voluntarily accepted.

The difficult questions as to the cases in which directors incur liability for the losses sustained by the shareholders whose affairs they have undertaken to manage, have often been raised in courts of law; but, hitherto, no satisfactory solution of them has been found. See JOINT-STOCK COMPANY. Of the statutory provisions as to directors contained in the joint-stock companies acts (consolidated in the act 25 and 26 Vict. c. 89), the chief are these: 1. That the first directors shall be selected, and their number determined, by the subscribers of the original memorandum of association, who shall themselves be deemed directors until other directors are appointed. 2. That his office of director shall be vacated by the acceptance of any other office or place of profit under the company, by bankruptcy or insolvency, or by being concerned in any contract with the company. 3. At the first ordinary meeting after the incorporation of the company, the whole of the directors shall retire from office; and at the first ordinary meeting in every subsequent year, one third of the directors for the time being, or if their number is not a multiple of three, then the number nearest to one third, shall retire from office. In every subsequent year, one third, or other nearest number, who have been longest in office, shall retire. A retiring director shall be re-eligible. 4. The company in a general meeting may increase or diminish the number of directors. 5. Any casual vacancy occurring in the board of directors may be filled up by the directors; but any person so chosen shall retain his office so long only as the vacating director would have retained the same if no vacancy had occurred. The company, in general meeting, may remove any director, and appoint another in his stead. 6. The directors may meet together for the dispatch of business, adjourn, and otherwise regulate their meetings as they think fit, and determine the quorum necessary for the transaction of business. 7. Questions arising are determined by a majority of votes, the chairman having a casting vote in case of equality. 8. A director may at any time summon a meeting of directors. 9. The directors elect their own chairman, and determine the period of his office. In case no chairman has been appointed, or he is absent, the directors shall appoint one of their number to preside for that time only. 10. Directors may delegate their powers to committees of such number as they may judge expedient. 11. The directors must cause minutes to be made in books provided for the purpose. These minutes shall set forth all appointments of officers made by the directors, the names of the directors present at each meeting of directors or of committee, all orders made by meetings or committees, and all resolutions and other proceedings of these bodies. These minutes shall be signed by the chairman, and shall be receivable in evidence of what took place without any further proof. 12. The directors, with the sanction of the company in a general meeting, may declare that a dividend shall be paid to the shareholders in proportion to their shares. No dividend shall be payable except out of the profits arising from the business of the company. 13. If the directors shall declare any dividend when the company is known by them to be insolvent, or any dividend the payment of which would, to their knowledge, render it insolvent, they shall be jointly and severally liable for the debts of the company then existing, and for all that shall be thereafter contracted, so long as they shall respectively remain in office. It is provided that the amount for which they shall be so liable shall not exceed the amount of the dividend declared, and that if any of the directors were absent at the time of making the dividend, or protested in writing, they shall be exempted from liability. Before recommending a dividend, the directors may set aside a reserved fund out of the profits of the company. In companies incorporated for carrying on undertakings of a public nature, such as railways, the appointment, rotation, and powers of directors, are regulated by the statute commonly called "The Companies Clauses Act," 8 Vict. c. 16 (for Scotland, c. 17). Two directors are sufficient to sign a contract. The directors have the management and superintendence of the affairs of the company, and may lawfully

exercise all the powers of the company, except such matters as are specially directed to be transacted by a general meeting of the company. See LIABILITY (LIMITED) ACTS, JOINT-STOCK COMPANIES.

**DIRECTORY.** On the death of Robespierre, in 1794, a reaction commenced in the convention itself, as well as throughout all France, against the sanguinary excesses of the Terrorists. Ultimately a new constitution—that of the year 3 (1795)—gave birth to a new government, composed of a legislative body divided into two councils—the council of five hundred, whose function was to propose laws; and the council of the ancients, whose function was to pass them. The actual executive power was intrusted to five members chosen from both sections, and who sat at the Luxembourg. Their names were Légeaux, Letourneur, Rewbel, Barras, and Carnot. These five constituted the famous *Directory*. They assumed authority in a moment of immense peril. France was environed with gigantic adversaries, while distrust, discontent, and the malice of rival factions made her internal administration almost hopeless. The frantic heroism of her soldiers saved her from spoliation by the foreigner; and had all the members of the D. been patriotic and honest, she might have been saved also from spoliation by her own children. But, on the contrary, the home-policy of the D. was deplorable. The demoralization which had begun to characterize officials even in Danton's time, now seized almost every class. Barras, a representative of all the turpitude of the hour, set the example. The majority of the two councils were equally corrupt; and although there were some both in the councils and D. whose virtues and talents were unimpeachable, yet they were too weak to counteract the knavery of their associates. It soon became clear that France could not be reconsolidated by the rag-ends of the revolution. The power and skill requisite for such a herculean work must be sought for elsewhere, among men who had received a nobler discipline than could be obtained in the political squabbles of the metropolis. Such was the thought of the abbé Sièyes. He turned his eyes to the army, where a host of new and brilliant names had appeared—Hoche, Joubert, Brune, Kleber, Desaix, Massena, Moreau, Bernadotte, Augereau, Bonaparte. Sièyes propounded his plan for the overthrow of the D., and the establishment of a consulate, that should be, in reality, a monarchy under republican forms, first of all to Moreau, who was frightened by its audacity; then to Bernadotte, whose excessive caution hindered him from approving of it; then to Augereau, who could not understand it; and finally to Bonaparte, on his return from Egypt. The last admired the project; a conspiracy was rapidly formed; all those functionaries who had been promised places by the D., but had not received them, offered their aid; and by the *coup d'état* of the 18th Brumaire (q.v.), an end was put to a government of weakness, immorality, and intrigue. It was succeeded by the consulate (q.v.).

**DIRECTORY FOR THE PUBLIC WORSHIP OF GOD**, a code of regulations concerning the different parts of public worship, drawn up by the Westminster assembly in 1644, ratified by the English parliament in the same year, and adopted by the general assembly of the church of Scotland and by the Scottish parliament in 1645. It was on express order from both houses of the English parliament, that the Westminster assembly addressed itself to the work of preparing this directory, to supply the place of the Book of Common Prayer, which had been abolished. In Scotland, it was hailed as conducive to "a happy unity and uniformity in religion among the kirks of Christ in these three kingdoms, united under one sovereign," and to "the corroboration of peace and love between the kingdoms." Many of the regulations of the directory are still complied with in all branches of the Presbyterian church in Scotland, but in many things it has been generally departed from; and a disposition prevails in almost all quarters to allow greater freedom and variety in the forms and unessential circumstances of worship; whilst many esteem a departure from the requirement of unnecessary *uniformity* in these things, as tending not a little towards the healing as well as the prevention of divisions, and the establishment of a real *unity*, and even as more consistent with the first principles of Presbyterianism.

**DIRECTRIX** is a right line perpendicular to the axis of a conic section, in reference to which its nature may be defined. Assume an indefinite straight line as the D. and a point without the D. as the focus. Then, if a line be revolved about the focus, any point moving in the line will generate a curve which will be a conic section when there is a constant ratio between the distance from the point to the focus and the perpendicular distance from the point to the directrix. The curve is an ellipse, a parabola, or an hyperbola, according as the distance from any point of the curve to the focus is less, equal to, or greater than the perpendicular distance from the point to the directrix. The constant ratio referred to is called the determining ratio of the conic.

**DIRK** is a short dagger which at various times and in various countries has been much used as a weapon of offense. In the royal navy, at the present day, it is worn by officers rather for ornament than for use, belted and buckled to the left side.

**DIRK-HARTOG ISLAND**, measuring 45 m. by 10, lies off the w. coast of Australia, in lat. 26° s., and long. 113° east. Along with two smaller islands to the n., all the three having their lengths parallel with the mainland, it forms the breast-work of Shark's bay, one of the most commodious inlets on that coast.

**DIRSCHAU**, a t. in Prussia, in the government of Dantzic, on the Vistula, a railway junction, 20 m. s.e. of Dantzic; pop. '75, 9,727. There is considerable trade

and industrial activity; but the chief claim of the place to attention is the lattice-work iron bridge over the river, built in 1850-57, 2,726 ft. long, with six spans of 410 ft. each. It affords passage for the railway between Königsberg and Berlin, for two ordinary carriage roads, and two sideways for foot passengers.

**DIRT-BEDS**, the quarrymen's name, introduced into geology, of several layers which occur in the lower Purbeck beds (q.v.), having the appearance of black dirt. They rest on the fresh-water beds of the lower Purbeck, and consist of one principal layer, from 12 to 18 in. thick, and from two to four thinner layers. The substance is, to a large extent, a dark-brown or blackish earthy lignite, being the remains of an ancient vegetable soil. Through it are dispersed, in considerable abundance, rounded fragments of stones from 3 to 9 in. in diameter. Fossil cycads and zamias are the predominant vegetable remains; they occupy their original upright position, having become fossil on the spots where they grew. The stumps stand erect for a height of from one to three, or even more feet, and at distances from each other similar to what may be observed in a recent forest. Besides these, the dirt-bed contains the silicified stems of coniferous trees, laid prostrate in fragments 3 or 4 ft. in length. The marine oolitic limestone, called Portland stone, was overspread with fluvialile mud, which became the soil on which a forest of cycads and zamias grow, and this was afterwards submerged without any violent agitation, since the layer of black earth has not been abraded, and then was covered with standing fresh water, from which the beds of calcareous mud, now converted into slate, were deposited.

**DISABILITY**, **LEGAL**, is either absolute, which wholly disables the person from doing any legal act—e.g., outlawry, excommunication, attainder, alienage—or partial, such as infancy, coverture, lunacy, drunkenness, and the like. It may arise from the act of God, of the law, of the individual himself, or of his ancestor, or the person from whom he inherits.

**DISASSIMILATION**. See **NUTRITION**.

**DISBANDING**, in military matters, is the breaking up of a regiment or corps. When peace is proclaimed after a war, and a reduction of the army becomes necessary, this is effected by disbanding or disembodifying; the men are discharged, and the officers are mostly placed on half-pay.

**DISBAR**, the degradation from the rank of barrister-at-law. This power is in England reposed in the benchers of the four inns of court. As the courts of law require that every barrister, before he is allowed to practice, must have been admitted to that office by one of the inns of court, so they will refuse to hear any one who has been deprived of his rank by the same authority. The power has rarely been exercised, and only when the conduct of the offending party has been grossly irregular. There can be no doubt that the high position held by the bar has been in great measure sustained by the code of honor administered by the societies of the inns of court—a code by which those who are by nature devoid of the feelings of gentlemen are obliged, outwardly at least, to recognize and to observe the demeanor of gentlemen. For some time this wholesome censorship had been exercised with less vigilance than formerly, but a case of disbarring occurred in 1862, and another in 1874.

In Scotland, the power to disbar rests in the faculty of advocates (see **ADVOCATES**).

**DISCHARGE**, from the military service, is by right at the expiration of the period for which attested; or earlier, by indulgence. In the latter case, the grant may be gratuitous, as on reduction of numbers, or when the man is not worth retaining, or paid for by the man discharged. In the last case, the soldier pays a sum of money computed with reference to the unexpired period of service. If a soldier has many years still to serve, the discharge purchase may amount to as much as £20. In the sappers and miners, where the men are all artisans, it may amount to £35; and among this corps such discharges are very frequent, on account of the value placed on the services of these intelligent men by private employers. Soldiers are, under the act of 1870, frequently discharged from service in the regular forces, after three or six years therein, on condition of serving the remainder of their original term in the reserve. Earl Grey, when colonial secretary, introduced the plan of enabling discharged soldiers to settle on a piece of land in the colonies instead of returning home.

Soldiers are occasionally "discharged with ignominy," for some offense that brings dishonor on the corps. In such case, the regiment is assembled, the crime recapitulated, and the sentence read. The buttons, facings, chevrons, medals, and all decorations, are cut from the man's uniform, and he is "drummed out" of the regiment, if a foot-soldier, or by sound of trumpet, if it be a cavalry regiment. Notice of his degradation is afterwards sent in writing from the war-office to his parents or relations.

**DISCHARGING**, in the royal navy, is the process of placing a ship "out of commission." A regiment of soldiers is permanently in pay, whether engaged in active service or not; but the crew of a ship are paid wages only so long as their names are on the books of a ship "in commission." Naval officers, too, are on full pay only so long as they belong to a particular ship in commission.

**DISCIPLES OF CHRIST**, a denomination of Baptists, organized 1827, who are often spoken of as Campbellites, but prefer to call themselves **THE CHURCH OF CHRIST**. In 1808, Thomas Campbell, a minister of the "Seceders," emigrated from Ireland to

the western part of Pennsylvania, and was followed, the next year, by his son Alexander. They both earnestly desired reforms in the Christian church conforming it to apostolic precept and practice. Their first step was to gather a small company of disciples for the special study of the Scriptures, with the pledge that, rejecting all human creeds and confessions of faith, they would strictly conform their practice to the teachings of the divine word. This virtual separation from the Seceders was followed by the gathering of a small congregation in Washington co. Penn., known as the Brush Run church, of which Thomas Campbell was an elder, and by which Alexander was ordained to the ministry. After what they regarded as a thorough investigation of the question of baptism, both father and son, with five other persons, feeling convinced that the Scriptures taught the "*immersion of believers*," were, June 2, 1812, immersed by a Baptist minister. In 1815, having increased to such a degree that they numbered 5 or 6 congregations, they united with the Redstone Baptist association, having first stipulated in writing that no terms of union or communion other than the Holy Scriptures should be required. As many of the Baptist ministers were, from the first, dissatisfied with this union the reformed congregations at length withdrew and joined the Mahoney (Ohio) association, the members of which regarded the new movement with favor and finally entered heartily into it. In 1823, Alexander Campbell commenced the monthly publication of the *Christian Baptist*, by means of which, together with public oral debates on baptism and itinerant preaching over large districts, his views were widely diffused among Baptists. Opposition to them on the part of many at length resulted in ecclesiastical action; the Dover association of Virginia, 1827, leading in what soon became a general withdrawal of Baptist fellowship from all who held the views of Alexander Campbell. The reformers, as they were called, then formed a separate organization, and have since rapidly increased, particularly in Kentucky, Ohio, Indiana, Illinois, Missouri, and Virginia. They have churches, also, in Canada, England, Wales, Ireland, and Australia. They now report about 2,000 ministers, 2,400 churches, and 500,000 members in the United States. Rejecting creeds and confessions of faith, as of human origin, they take the Bible as the sufficient and only authority in matters of faith and practice. Shunning subtle theological speculations, they aim to present Bible truths in Bible terms. This exposed them at first, and in some quarters, to the imputation of holding Unitarian views; but their orthodoxy on this portion of theology is now fully admitted. On the atonement, resurrection, and general judgment they agree with the great body of evangelical Christians. They continue the breaking of bread in commemoration of the Savior's death every first day of the week. They hold that faith and repentance are the divinely appointed pre-requisites for baptism, and that all who do repent and believe may and should be immersed in the name of the Lord Jesus Christ for the remission of sins and reception of the gift of the Holy Spirit. In church polity they are congregational, with three classes of officers: 1. elders, presbyters, or bishops; 2. deacons; 3. evangelists. The last named are the itinerating ministers or missionaries, and are supported by voluntary contributions. Acknowledging their obligation to provide for the wide diffusion of scriptural preaching by well-instructed men, they are zealous in promoting education. They have a university at Lexington, Ky.; and colleges at Bethany, West Va.; Hiram, Ohio; Franklin, Pa.; Indianapolis, Ind.; Eureka, Ill.; and Oskaloosa, Iowa; besides colleges for women and many other schools of high grade.

**DISCIPLINE, FIRST BOOK OF, OR OF POLICY**, in Scottish ecclesiastical history, an important document, drawn up by John Knox and four other ministers, in 1560. Along with the confession of faith of the same year, it must be held as exhibiting the principles on which the reformed church of Scotland was originally founded. It lays down rules for the election of "pastors or ministers" by the congregation, their examination by "the ministers and elders," etc., also for the election of elders and of deacons; it recognizes the office of superintendent (q.v.) as then established; but it is most largely occupied with things pertaining to ecclesiastical discipline, strictly so called, and the mode of dealing with persons guilty of offenses. The first book of discipline never received the sanction of parliament, but was subscribed by many of the nobles and barons.

**DISCIPLINE, SECOND BOOK OF, OR "Heads and Conclusions of the Policy of the Kirk,"** a document of great importance in the ecclesiastical history of Scotland, adopted by the general assembly in 1578; and, although never ratified by act of parliament, still frequently appealed to as the most perfect and authoritative exhibition of Scottish presbyterianism. The separations which have taken place from the established church in Scotland, have not been on the professed ground of dislike to the constitution exhibited in the second book of discipline, but of anxiety for its perfect maintenance; and this document has recently been adopted as one of the articles of union among Scottish Presbyterian churches in Australia. It was prepared with great care by a committee of the general assembly, in which Andrew Melville took a leading part; and in a time of much conflict between the court and the church, concerning the power of the civil government in things ecclesiastical, church government, and patronage (q.v.). It begins by asserting strongly the powers regarded as essentially inherent in the church, sets forth the distinctions between civil and ecclesiastical government and their mutual relations, and lays down a thoroughly Presbyterian platform of church-government.

**DISCIPLINE**, in naval and military matters, is a general name for the rules laid down for the proper behavior of the persons employed. The mutiny act, the articles

of war, and general orders issued by the admiralty and the war office, form collectively the code by which discipline is regulated. See ARTICLES OF WAR, MUTINY ACT.

In the army, regimental discipline is chiefly maintained by the adjutant. He sees the regimental orders carried out; superintends the drill and field movements; inspects and tells-off all guards, escorts, and parties; regulates all duty rosters, or rollsters; receives garrison orders; keeps regimental books. The adjutant-general is to the whole army what the adjutant is to a regiment, in reference to discipline. In the navy, the discipline is necessarily very strict.

**DISCOBOLI**, according to Cuvier, a family of malacopterous fishes, remarkable for having the ventral fins united to form a sucking disk on the under surface of the body. To this family, also called *cyclopteridae*, belong the lump-sucker (*cyclopterus lumpus*), the unctuous sucker or sea-owl or cock-paddle *snail*, and or two other British fishes. To this family Cuvier also referred the remora (q.v.), adverting, however, to the different position of the sucking disk, and other important distinctions, on account of which a very different place in the system is now assigned to it. The use of the sucking disk, however, is much the same—that of attaching the animal to fixed substances, so that it may remain and obtain its food, where otherwise it would be swept away by the current. The adhesive power of the sucker, in the larger specimens of the lumpfish, remains after death.

**DISCORD**, sounds which have no harmonical relation whatever; differing from dissonance (q.v.), which in musical language is applied to sounds that are in grammatically correct relation to each other, though not consonant.

**DISCOUNT**, the difference between a sum of money due at a future period and its present value; or the deduction made from the amount of a debt that is paid before it is due. It is usually ascertained—in the case of bills of exchange, promissory notes, and the like—by subtracting from the principal amount its interest, calculated from the date of payment until the date when the amount is due; but this, although sanctioned by usage, leads to an excess of charge, the interest being thus advanced to the lender before it has actually accrued. True discount is computed as follows: Suppose that £100 is advanced for one year at, say 5 per cent, the sum repayable at the end of the year in respect of this advance will be £105; therefore, £100 is the present value of £105 due a year hence; and from this conclusion it is easily deduced by proportion, that the value of £100 due a year hence is £95 4s. 9½d. Hence the true discount on £100 due in a year at 5 per cent, is £4 15s. 2½d. The usual formulas are—for the present value,  $\frac{100A}{100+nr}$ ; for the discount,  $\frac{Anr}{100+nr}$ ; where “A” is the principal sum due; “n” the time, in years or fractions of a year; and “r” the rate per cent, *simple interest being assumed*. For example, let it be required to find the discount on £97 7s. 6d., due seven months hence, at 4½ per cent. Here A=£97 7s. 6d.=97.375,  $n=\frac{7}{12}$ ,  $r=4\frac{1}{2}$ ;  $nr=\frac{7}{12} \times 4\frac{1}{2} = \frac{21}{8} = 2\frac{5}{8}$ .  $Anr=97.375 \times 2\frac{5}{8}$ .

$$100+nr=100+2\frac{5}{8}=\frac{821}{8}$$

Hence the discount is  $\frac{97.375 \times 2\frac{5}{8}}{\frac{821}{8}} = \frac{97.375 \times 21}{821} = \frac{204.4875}{821} = 2.491 = £2 \text{ 9s. } 10\text{d.}$

But it is easier first to determine the present value, and hence, by subtraction from the amount due, the discount.

An extension of the above formulas is necessary in computations connected with leases, reversions, etc., to be valued on the stricter principle of compound interest, for which see INTEREST.

By discount is likewise understood the depreciation in value of a fixed investment; as when a railway share, on which say £100 has been paid, can be sold for £90 only, the “discount” being thus 10 per cent.

The allowance made to a trader, under the name of discount, for prepayment of a debt, is usually greater than the current rate of interest, as the creditor receiving the money before it becomes due, secures himself against the insolvency of the debtor.

The rates of discount vary according to the demand for money and the nature of the security. The range in Britain is from 3 to 10 per cent, except in the case of doubtful bills or post-obit bonds, when a much higher rate is exacted. Bills at and under three months’ currency are usually charged a per cent less than those of a long date. In the colonies higher rates are allowed.

**DISCOVERY, BILL OF**, a bill in chancery (q.v.) which prays the disclosure by the defendant of some matter pertinent to the cause of the plaintiff. By means of bills of discovery, the equity courts formerly possessed an advantage over the courts of common law in extracting evidence from the parties to a suit, who could not be examined as witnesses in an action at law. But by 14 and 15 Vict. c. 99, 16 and 17 Vict. c. 83, and 17 and 18 Vict. c. 125, parties to an action are competent witnesses, and must give evidence. See the judicature act (1875), ord. xxxi.

**DISCOVERY, BILL OF** (*ante*), commonly used in aid of the jurisdiction of a court of law to enable the party who prosecutes or defends a suit to obtain a discovery of the facts which are material to such prosecution or defense. The plaintiff must be entitled to the discovery which he seeks, and can have a discovery only of what is necessary for his own title, as of deeds under which he claims, but not to pry into affairs of the

defendant. The bill must show with reasonable certainty a present and vested title and interest in the plaintiff, and what that title and interest are; must state a case which will constitute just ground for a suit or defense at law, and describe deeds and acts with reasonable certainty. A bill of discovery will not lie in aid of a criminal prosecution, a mandamus, or a suit for a penalty.

**DISCUSSION**, in Scotch law. By the law of Scotland, all cautioners, unless bound jointly and severally with the principal debtor, were formerly, and cautioners bound prior to the passing of the mercantile law amendment act (21st July, 1856) are still, entitled to insist that the creditor shall call on the principal debtor in the first place; or *discuss* him, as it is technically said. Where the principal debtor fails to satisfy the obligation in full, the creditor was bound to give the cautioner the benefit of such portion of it as he did discharge. D. was not merely a demand for payment, but enforcement of it, in so far as the means of the principal debtor admitted of. Cautioners bound subsequently to the date of the mercantile law amendment act (19 and 20 Vict. c. 60, s. 6), can enjoy the right of D. only by express stipulation.

**DISEASE**, according to its literal construction, a state of *dis-ease*, or absence of the condition of health, in which all the faculties and organs of the body and mind work together harmoniously and without sensible disturbance. In a strictly scientific sense, there may be disease without pain or uneasiness in the ordinary meaning of these words, but hardly without functional disturbance or incapacity of some kind. It is, therefore, only necessary to include in the definition of disease the diminution of functional power, whether attended or not by suffering, and the scientific and practical ideas of the word will closely correspond. It must be admitted that slight structural and functional deviations from the state of health are sometimes unnoticed; but only because they are slight, and because the functions to which they extend are not habitually in use to the full extent. A great deal of unnecessary obscurity is found, especially in continental writers, in discussing the abstract idea of disease, which has been connected with all the most intangible subtleties of the most abstruse and metaphysical philosophy, by regarding it as dependent upon the idea of life and of the vital force. Many authorities have thus generalized disease into a separate active principle, opposed to, and everywhere seeking to destroy, the principle of health; and Paracelsus was hardly more open to objection on the ground of absurdity than many others of his countrymen, when, in his picturesque and at the same time mystical manner, he endowed the vital principle with a kind of personality, and spoke of disease as due to the whims and caprices of a displeased and resentful Archæus, an idea which was still further developed by Van Helmont. It is common to treat of disease as being *functional* or *organic*; i.e., evidenced by changes of function or of structure; but function and structure are so closely allied in fact and in nature, that the more this distinction is examined the more vague and impalpable it becomes; and it can therefore only be kept up as a provisional and conventional arrangement. The classification and arrangement of diseases according to their external characters has been termed *nosology* (q.v.); while the observation of their more intimate and less superficial relations in connection with their causes and results, is called *pathology* (q.v.); both of these sciences, of course, being kept in view in the healing art of medicine (q.v.), of the more practical portion of which they form the pillars.

**DISEASES, DISTRIBUTION OF.** It is generally known that the different regions of the earth are subject to diseases deriving their character from local circumstances and conditions, such as latitude, climate, the chemical quality of the soil, elevation of the land above the sea-level, variation of temperature, water distribution, character of the vegetation, and the peculiar habits of the people. The science of nosography in this aspect, however, did not receive much attention before the beginning of the present century, and is still comparatively undeveloped, though something has been done in the way of discovering and classifying facts. It is known that tropical regions are the home of malarial fevers, cholera, and hepatic diseases. This is due in part to the damp soil and decaying vegetation, particularly in the river valleys. The yellow fever of the Mexican gulf, though often aggravated by other conditions, doubtless originated primarily from this cause. In the more temperate zones, typhus, typhoid, intermittent, and scarlet fevers are found. They are, however, for the most part, not so much endemic as epidemic. In the northern hemisphere, n. of the tropical zone, catarrhal diseases prevail, while in the corresponding zone of the southern hemisphere they are unknown. Intestinal catarrh prevails, however, to a considerable extent in some parts of the intertropical regions. Nosologists are as yet unable to explain why some diseases prevail alike in widely different latitudes; for example, rheumatism in warm and dry as well as in cold and wet regions; and leprosy in Greenland, Norway, and Iceland, as well as in the tropics. In some cases, hilly regions are ravaged by fevers, while in the intervening valleys fevers seldom occur. The cultivation of the soil, sometimes essentially modifies the character of the malarial diseases. The destruction of forests often results in the introduction of diseases unknown before. Indeed, as a general rule, living vegetation tends to preserve health, while decaying vegetation is a prolific source of disease; but the modifications of this law are very little understood. Defective drainage, natural or artificial, is also a common source of disease, especially in cities and thickly settled towns. The personal habits of races and communities in respect to diet and

cleanliness, exert a wide influence upon the public health. Europe, on the whole, possesses the requisite conditions of health in greater perfection than any other quarter of the world. The rates of mortality from diseases of the lungs are greater in northern than in southern latitudes. This is illustrated by the prevalence of consumption in the north-eastern portion of the United States. Fevers are more prevalent in the southern than in the northern states. Malarial fevers are especially fatal in the southern regions of the country. They are infrequent, however, where pine forests abound. Knowledge on this subject, as yet fragmentary, is slowly increasing.

**DISEASES OF PLANTS** form a subject of study interesting equally in its scientific and its economic or practical relations, but in regard to the most important parts of which much obscurity and uncertainty still exists. Enough, indeed, is known to show that, as might have been expected, an analogy subsists between the kinds of disease to which plants are subject, and those of animals, both in their nature and their causes, yet with wide differences, according to the difference between vegetable and animal life. Plants, like animals, are liable to suffer from unsuitable external circumstances, as of temperature, drought, or moisture, etc.: they are liable, like animals, to suffer from deficiency of food, from excess of it, or from being compelled to subsist on improper kinds of it, or too exclusively on some particular kind. They often suffer much from vegetable parasites, chiefly fungi, and from multitudes of minute animals, which, without eating them up, destroy organs essential to their health, or prey upon their juices. The constitutions of plants are accommodated to particular temperatures, and they neither flourish when the temperature is for any considerable time much above or much below certain limits, very different, however, for different species. Light is of the greatest importance to vegetable life, and a want or deficiency of it speedily produces an unhealthy condition, the proper chemical changes not taking place in the juices of the plant; and this unhealthy condition, sometimes very extensively produced in gloomy seasons, when the deficiency of light is accompanied with excess of moisture both in the air and in the soil, renders plants very liable to the attacks both of vegetable parasites and of minute animal tribes.

Excess of nutriment, causing an extreme rapidity of growth, sometimes produces an unhealthy condition in particular parts of plants, in which a greater amount of tissue is developed in a single season than can be thoroughly matured.—Manures, injudiciously and unsuitably applied, are often productive of disease. Putrescent matter coming in contact with the roots of many plants, is very injurious to them, and causes *canker*.—Contagion, as a cause of disease in plants, if not fully demonstrated, is rendered highly probable by such facts as the memorable prevalence of the potato disease, and the rapid spread of the vine disease (*oidium*); nor does the existence of particular fungi in the diseased plants materially affect this probability.

With regard to the diseases of plants generally, little has been hitherto found practicable in the way of cure, and prevention is the object chiefly aimed at in all investigations of their nature and causes.

Some of the most important diseases of plants are noticed under particular heads; and some of the most destructive parasitic fungi are described in their proper places in this work.

**DISHONOR OF A BILL.** When the drawee, or person on whom a bill is drawn, declines to accept it or to pay it, he is said to dishonor it. The act of drawing or of indorsing a bill implies an obligation to pay it in the last instance, and the person in whose favor it is drawn has thus recourse against the drawer and indorsers, should the drawee fail to accept or to pay. In order to preserve this recourse, however, it is indispensable that notice of dishonor shall be given to the drawer and indorsers. No particular form of notice is requisite. The notice must be such as to identify the bill, and to inform the party to whom it is given of the protest, a copy of which ought to accompany it. If the notice is put into the post-office, and properly addressed, it is sufficient; and even verbal notice, if clear, will suffice. In the case of foreign bills, the period within which notice must be given is regulated by the usages and customs of merchants. Any delay which can fairly be ascribed to neglect or omission, and is not justified by the circumstances of the case, will be fatal to the bill-holder's claim for recourse. In inland bills and notes, the rule till lately in Scotland was, that fourteen days after the protest was taken should be allowed. This has been altered by the mercantile law amendment act (19 and 20 Vict. c. 60), which provides (s. 14) that notice of dishonor of inland bills and promissory-notes, in order to entitle the holder to recourse, shall be given "in the same manner and within the same time as is required in the case of foreign bills by the law of Scotland." To both classes of bills, then, the English rule is now applicable, which is, that notice must, in the general case, be sent the next day, where the parties reside in the same place, and by the next post, if they reside at a distance.

**DISINFECTANTS** are a class of substances which have the power of absorbing or destroying the effluvia or fetid odors evolved from putrescent matter, and the miasmatic matter generated in low, marshy, and ill-drained localities. The principal substances capable of being used for this purpose are chlorine, bleaching-powder, carbolic acid, animal and wood charcoal, chloride of zinc, sesqui-chloride of iron, nitrate of lead,

acetate of lead, and nitrous acid. Chlorine (q.v.), either when used by itself, or in combination with lime, as bleaching-powder, is probably the most powerful disinfecting agent. When liberated into an apartment, it immediately causes the destruction of infectious or other deleterious matters. The mode of its action appears to be principally due to the great affinity of chlorine for the hydrogen of the gaseous compounds evolved from putrefying matter, and in abstracting the hydrogen, the chlorine destroys the organic substance. A simple way of employing chlorine as a disinfecting agent in sick-rooms, and adjacent lobbies and apartments, is to place a thin layer of bleaching-powder upon a plate, from which the carbonic acid of the air will liberate chlorine rapidly enough to be of essential service in keeping down infection, and without causing any inconvenience to the inmates. If a more plentiful supply of chlorine be desired, a little vinegar added to the bleaching-powder will liberate the gas freely. Charcoal is also of great service in removing fetid effluvia. Clothes possessing a disagreeable odor may be deprived of it by being rolled up or placed in a box with charcoal; and a thin layer of the latter strewn over putrefying matter, such as the decomposing carcass of an animal, immediately absorbs the effluvia, and the air above becomes quite sweet. The charcoal acts first by absorbing the odoriferous gases, such as ammonia, hydro-sulphuric acid (sulphuretted hydrogen), etc., and thereafter aids in the oxidation of these into nitric acid, sulphuric acid, and water. As agents capable of being employed in the deodorization and purification of offensive liquids, such as biige-water and sewerage-water, there are chloride of zinc—Burnett's disinfecting liquid (q.v.)—chloride of manganese, perchloride of iron (Ellerman's deodorizing fluid), and nitrate of lead (Ledoyen's disinfecting fluid); but these liquids are not true disinfectants, and are merely serviceable in deodorizing by *fixation*. The employment of fumigating pastilles, burning brown paper, and fumigations with camphor, benzoin, mastic, amber, lavender, and other odoriferous substances, is merely serviceable in cloaking over the offensive, fetid, and hurtful gases, and should never be resorted to unless in conjunction with the use of other agents possessing the properties of true disinfectants. See CARBOLIC ACID; and, for Condy's fluid, the article MANGANESE.

**DISINFECTANTS** (*ante*). The subject of disinfectants is not yet perfectly understood, and there are many unsettled notions regarding it. There has lately been considerable skepticism in regard to the disinfecting powers of chlorine and carbolic acid, and with apparently good reason. Doubtless too much reliance has been placed upon them, or upon an inefficient mode of using them. The mode of action of chloride of lime, or the chlorine or chlorine compounds liberated therefrom, is probably like that in bleaching. The disease-breeding organism is broken up, and consequently its propagating power destroyed, just as coloring matter is broken up. This explanation does not take into consideration, of course, the theory of bleaching which supposed the abstraction of hydrogen by the chlorine compound and the liberation of oxygen in the condition of ozone. The important fact to bear in mind is that the disinfectant destroys the disease germs. Now, to act in this way, it is necessary to have at least one molecule of the disinfectant in the presence of one molecule of the disease-producing organism, and probably it requires several, perhaps a hundred to one. The question then arises how many molecules of matter or how many organic compound particles are there in a given number of disease germs. No positive answer can be given. It is a mere matter, not of guess-work, but of estimation, and involves the question as to how many molecules of the disinfecting material are required to produce the death or disorganization of the disease germs. After a number of experiments, the question can be, and has been, practically decided. It is found that when an apartment is thoroughly fumigated with chlorine, or the compounds liberated by chloride of lime, that disease germs are destroyed. If, however, chloride of lime has simply been strewed about the premises, even in considerable quantity, it is found often that the place has not been thoroughly disinfected. If carbolic acid is used in too weak a solution it may not sufficiently arrest or destroy the vitality of the growing disease germs. To depend upon the fumes of carbolic acid would be a practical fallacy. The substance must be directly applied, as a rule, to have a full sanitary effect. Perhaps chlorine may act by simply killing the germs. Carbolic acid probably does, and some other substances of less power may act upon some disease germs sufficiently, when they are not present in too great quantity, to prevent development of disease. Heat and cold, when intense enough, are perfect disinfectants. The continued application of dry air heated to 150° or 200° will generally destroy disease germs. It doubtlessly desiccates them, and they die. Moist air must be heated to the boiling point to produce the same effect. A sufficient degree of cold will also effect the purpose; how great, cannot be stated for every instance. We know that diphtheria and scarlet fever, particularly the latter disease, often flourish in severe cold weather. The application of cold, except in a limited and partial manner, is impracticable. The mode of disinfecting any given locality must depend upon circumstances, and often requires much judgment. See CARBOLIC ACID, *ante*.

**DISK**, in botany, a part intervening in some flowers between the stamens and the pistil. It seems in most cases to represent an inner whorl of stamens variously modified. It is often a mere ring; sometimes it exhibits a whorl of scales or of rudimentary

stamens, or even of petal-like appendages; sometimes it rises into a sort of cup around the pistil; sometimes, as in the rose, it assumes the form of a waxy lining of the tube of the calyx. It is often glandular, and secretes a honey-like fluid. It is one of the parts included under the vague comprehensive term *nectary* by the older botanists.

#### DISK AND DISCOBOLUS. See QUOIT.

**DISLOCATION** consists in the displacement of one bone from another with which it forms a joint (*put out of joint* being the popular expression). Dislocations are generally the result of sudden accident, but may be the result of disease, or may be congenital. The displacement may be *partial* or *complete*; and surgeons classify their cases into *simple* dislocations, when the skin remains unbroken, and compound, when there is a wound by which the external air may communicate with the joint. Occasionally, in addition to the dislocation, there are fractures of the bones, or lacerations of important blood-vessels in the neighborhood; it is then termed a complicated dislocation. Dislocation is a rare accident in infancy and old age, because in the former the joint-ends of the bones are very flexible, and yield to violence; while the aged skeleton is so rigid that the brittle bones fracture under force that would drive younger and firmer ones out of their sockets. Dislocations are most frequent between the ages of thirty and sixty. Persons with weak muscles, and lax, long ligaments, or those in whom the latter have been softened by inflammation of the joint, are predisposed to dislocation. The joints most frequently displaced are the shoulder and the elbow.

*General symptoms of a dislocation.*—After a blow, fall, or violent muscular exertion, a limb is found to be immovable at the injured joint, there is great pain, and the shape of the part is changed; but soon swelling ensues, and every distinctive mark about it is obscured. If left alone, or merely treated as an inflamed joint, the swelling gradually subsides; but the immobility continues, the limb is crippled for months or years, when at last nature forms a new socket for the end of the bone, and some amount of useful motion is restored. The proper shape of the part is never restored, but remains an eyesore to the patient, and a disgrace to the surgeon.

*The general treatment of dislocations* consists in their *reduction*, or pulling the displaced bone back into its place. Its return is opposed by the muscles attached to it, which are stimulated to contraction by the pain of the operation, which requires, of course, a good deal of force to be employed. It is desirable to remove this spasm of the muscles, which is the great obstacle to the reduction of a dislocation; and in former days, bleeding from the arm, emetics, the warm bath, etc., were generally made use of; nowadays, chloroform or ether attains the same ends, and renders the treatment of dislocations much more simple and humane than before the introduction of anæsthetics.

When the surgeon is about to reduce a dislocation requiring any degree of force, he fastens the part of the limb above the displaced bone or the trunk, so as to afford him *counter-extension*; he then pulls on the limb either with his hands, or with a bandage or handkerchief attached to it. The best way of fastening this is to roll a bandage, wetted, to prevent slipping, round the limb, and then taking the thing with which he wishes to extend in both hands, he casts it into two loops, forming what is called a *clove-hitch*, and then slips the double noose up the limb till it rests on the wet bandage previously applied. In old-standing cases, the hands grow weary before the extension has been kept up sufficiently long, so it is well to adapt pulleys to draw upon the clove-hitch, as with them the traction can be regulated as the surgeon desires. Sudden, forcible pulling is useless and hurtful, the object being merely to tire out the muscles which resist the attempts at reduction; when they are exhausted, the bone will generally slip back into its place with an audible snap.

A class of shrewd individuals, called "*bone-setters*," frequently derive profit from some conditions of joints which resemble dislocations. Chronic rheumatic inflammation is occasionally known to fix itself by an accident on some particular joint, especially the shoulder or hip, and may so change the surfaces of the bone-ends that they are spontaneously dislocated; the empiric, naturally antagonistic to the regular practitioner, tells the patient that when he met with the accident the dislocation occurred, but that his doctor overlooked it. Again, many persons who have injured their joints do not submit to having them moved about after the first inflammation has subsided. The bone-setter gives a forcible bend to the limb, which breaks up the adhesions; and because he has done roughly what the doctor would have done equally well gently, the patient praises him, while he blames the one who guided his joint in safety through the first effects of the accident.

Whenever a dislocation occurs, the nearest medical man should be summoned, even should the mere displacement be rectified at once, because no such accident can occur without some tearing of the soft parts, and it will depend on the after-treatment whether the joint will ever become useful again or not. It must also be remembered, that the sooner a dislocation is reduced, the easier is the reduction. Since the introduction of anæsthesia, however, and the subcutaneous division of tissues, many ancient cases may be improved, and many crippled limbs restored to usefulness.

**DISLOCATION**, or **FAULT**, a term used in geology to characterize certain displacements common among stratified rocks. The agency that raised these rocks above the waters of the sea, produced in the elevation numerous rents. In their simplest form,

the rents are mere cracks, the parts, though separated, remaining contiguous; sometimes a greater or less fissure intervenes between the disunited portions, and this is filled with materials pressed in from above, or with igneous rocks intruded from below. The beds, however, are not always found at the same level—a displacement as well as a severance often takes place, so that the beds on one side of the fissure or crack are many feet, or many hundreds of feet, above or below the beds on the other side with which they were once continuous. One of the best known faults is that called the “Ninety Fathom Dike” in the Newcastle coal-field. The same beds are 90 fathoms lower on the northern than they are on the southern side. The fissure varies in width from a few feet in some places to more than 20 yards in others; it is filled with sandstone. In the Edinburgh coal-field, the greatest fault is the one known as the “Sheriffhall Slip.” It has produced a dislocation of the strata to the extent of 400 or 500 ft., so that the coal which is worked on the s. side of the slip, near the surface, is on the n. side 500 ft. below it. Mr. Milne Home enumerates 120 faults in the Mid-Lothian and East-Lothian coal-fields. He has himself examined 78 of these, and has found that 35 dip to the s., and 43 to the n.; and that while the sum of the down-throws by the faults dipping to the s. is 385 fathoms, those dipping to the n. have depressed the strata 754 fathoms.

Faults in coal-fields are well known, because of their serious interference with the progress of the miner. But though they often cause considerable labor and expense in searching for the continuation of a valuable seam of coal, they have corresponding advantages, since they disclose on the surface the value of the buried minerals, and when filled with solid materials, they form embankments which confine water, and thus save considerable expense in draining the mine.

The amount of dislocation is the measure of a line drawn from one part of the bed, at right angles to its plane, to a line produced from the other separated part of the bed representing its plane. Although no notion can be formed, in meeting with a fault, of the extent of dislocation, yet the direction in which the lost strata are to be sought can be certainly determined, for it has been found to be an invariable law, that the strata are lowest on the overlapping side of the slip. Faults have local names from the miners, all of which have been used by geologists. They are called hitches, dikes, troubles, slips, slides, heaves, and throws.

**DISMAL SWAMP**, measuring 40 m. from n. to s. by 25 in breadth, lies chiefly in Virginia, but partly in North Carolina. In the center is lake Drummond, covering about 6 sq. miles. Elsewhere the surface is divided between tangled reeds and heavy timber, with a thick undergrowth. This extensive morass has been, at a vast cost, traversed lengthwise by a canal, which connects New Lebanon, in North Carolina, with Norfolk in Virginia.

**DISMANTLE** is the operation which a ship undergoes when to be laid up in ordinary, or placed out of service. She is unrigged; the rods and most of the ropes are removed; and the upper masts taken down.

**DISMAS**, *Str.*, the name which Catholic tradition has attached to the “good thief.” He is represented with a cross beside him.

**DISORDERLY HOUSE**. For this, see *NUISANCE*.

**DISPART**, in gunnery, is a mark set upon the muzzle of a gun, to aid the gunner in obtaining a line of sight truly parallel with the axis of the bore. The dispart, in strictness, is not the mark itself, but a distance or quantity denoted by the mark; and “to dispart” a gun is to determine this distance. It depends mainly on the relation between the diameter of the breech and that of the muzzle.

**DISPENSATION**, a license granted by the pope for that which is ordinarily prohibited. The nature and limits of the dispensing power have been the subject of much discussion not only in controversy with Protestants, but among Roman Catholics themselves. It is held by the extreme advocates of papal power, that the pope may dispense in any divine law, except the articles of faith; by others, that his dispensing power does not extend to express precepts of the New Testament; some say that his D. is valid only when it proceeds upon just cause; some, that it is not properly a relaxation of the law's obligation, but merely a declaration that in the particular case the law is not applicable. The usage of the church of Rome, however, agrees with the opinions of her theologians in making the pope supreme in releasing from oaths and vows; and a decree of the council of Trent anathematizes all who deny the power of the church to grant dispensations for marriages within the prohibited degrees of the Mosaic law; whilst the multiplied prohibited degrees of the canon law give much occasion for the more frequent exercise of the same power.—Nothing really of the nature of a D. is known in any Protestant church. The only kind of dispensations now in use in England, are those granted by a bishop to a clergyman, to enable him to hold more benefices than one, or to absent himself from his parish. Formerly, the pope's dispensations in England, as elsewhere, prevailed against the law of the land, not in ecclesiastical matters only, but in all that large department of civil affairs which, by an interested fiction, was brought within the scope of ecclesiastical government. This abuse was swept away at the reformation, by 25 Henry VIII. c. 21. The power of the pope was then conferred on the archbishop of Canterbury, in so far as it was not contrary to the law of God. The

granting of special licenses of marriage, and the like, is the only form in which it is ever exercised.

In former times, the crown claimed a dispensing power in civil, similar to that which belonged to the pope in ecclesiastical matters. The power was grossly abused by James II., and was consequently expressly abolished by the bill of rights. The privilege of granting pardons in capital cases is the only form in which the dispensing power of the crown still exists.

**DISPERSION.** Ordinary white light is heterogeneous in its character, being composed of rays of different refrangibility, and the term D. is used in optics to denote the separation of these rays by refraction. Transparent media of various kinds possess different dispersive powers, or, in other words, different powers of widening the angle between the red and violet rays, when a ray of white light suffers refraction through a prism of given angle at a given angle of incidence. The circumstance called the "irrationality of dispersion," consists in the fact, that when a spectrum is measured after Fraunhofer's manner, it is found that the distance between any of the same two fixed lines of the spectrum has not a constant ratio to the distance between the extreme fixed lines, where different media are used. See SPECTRUM. It may be noticed that the word D. is also sometimes used to denote in optics irregular reflection or the scattering of light on imperfectly polished surfaces. See CATOPTICS. The amount of light not reflected according to the regular law varies with the nature of the reflecting surface. In the case of light incident at right angles upon a surface of common glass,  $\frac{1}{8}$  only is properly reflected. In perpendicular reflection at an ordinary silvered looking-glass, about  $\frac{1}{2}$  is lost by this sort of dispersion. A little less than  $\frac{1}{2}$  is lost in perpendicular reflection from highly polished speculum metal.

**DISPLAYED**, in heraldic usage, means *expanded*; as an eagle displayed, or what is vulgarly known as a spread eagle. See EAGLE.

**DISPOSITION**, in art, differs from *composition*, inasmuch as the former has reference to the arrangement of the parts, the latter to the effect of the whole.

**DISPOSITION**, in music, a term now used in organ-building, adopted from the German, meaning the arrangement and combination of the stops on the different rows of keys and pedals, with the pitch of each stop, or length of the lowest CC pipe.

**DISPOSITION**, in the law of Scotland, is a deed of conveyance, applicable either to heritable or movable property, but most frequently used for the purpose of transferring the former from the seller to the buyer. There is another well-known form of the deed, the object of which is to settle a whole succession, both heritable and movable, a will or testament, in Scotland, being used mostly for movable property. This latter deed is commonly known as a disposition and settlement. The following are the clauses usually contained in a disposition for the purpose of conveying heritable property: 1. The *narrative* or *inductive* clause, in which the names of the disponent and disponente are set forth, the cause of granting the deed is stated, and the receipt of the price or consideration is acknowledged, if the conveyance has been for an onerous cause. 2. The *dispositive* clause, in which the maker of the deed "sells and disposes," or "gives, grants, and disposes," if there has been no price paid or consideration given. 3. A clause obliging the disponent to infest. See INFESTMENT. 4. A procuratory of resignation. 5. A clause of warrandice (q.v.). 6. An *assignment* to the title-deeds and rents of the subject. 7. An obligation to free the disponent from public burdens due before his term of entry. 8. A clause to the effect that the title-deeds have been delivered to the disponent. 9. A clause of registration. 10. A precept of sasine (q.v.). And lastly, a testing clause (q.v.). Though it is still optional to make use of these clauses, they have been greatly shortened, and in some instances dispensed with by recent acts, which are consolidated by the titles to land (Scotland) act (1868). 31 and 32 Vict. c. 101, and 32 and 33 Vict. c. 116. A disposition for the conveyance of movables is a much simpler document. It often bears reference to an inventory containing a more particular enumeration of the effects conveyed. It grants power to the disponent to take possession of the subjects, and it also contains clauses of warrandice and registration, and a testing clause. The disposition and settlement, again, varies in form according to the nature of the property conveyed, and the arrangements which are made with reference to it. Sometimes it is a direct conveyance; in other cases it conveys the property to trustees, to be held and administered by them for the benefit of other parties. In this latter case, it is known by the name of a trust-disposition and settlement. Where contingencies which cannot be foreseen with certainty are anticipated, where the management is complicated by details, or where the operations under the deed are likely to be protracted, the appointment of trustees (see TRUST) is usually resorted to. In either case, the grantor's life-interest in the property is reserved in express terms, and there is also a clause dispensing with delivery. The word "dispone" used to be considered a vital word in all these deeds, but is now no longer essential, though it is still current. A disposition in security, which corresponds to the English mortgage, will be explained under heritable securities.
